Mr. Huggin's recent comparisons of the spectroscopic appearances of comets and incandescent portions of meteoric stone show the presence in both of hydrogen and nitrogen compounds, confirming the conclusions drawn from the identity of the path of comets and meteoric shooting stars.

From all these and other considerations, it is allowable to suppose that the earth and moon, when they separated from the solar nebula, did so in the form of solid meteoric stones, each of them having the temperature of interstellar space—that is, something not much warmer than 460° Fahr. below the freezing point of water.

Some Newly Observed Properties of Glucose.

Among the many fluctuating observations formerly made regarding glucose were the following important ones: First, the reduction of alkaline copper solutions; second, the absorption of alkali in a titered solution. To these Leon Cnisinier adds the following new ones:

If a dilute solution of glucose which is saturated with lime be left standing for a long time, the rotary power decreases more and more, without passing beyond the light orange color. After a larger portion of its rotary power has disappeared, only a comparatively small part of the alkali is absorbed. If it is saturated with carbonic acid, it will be found that its power of reducing a copper solution has not perceptibly altered in comperison with what it was at the start, while its rotary power has disappeered entirely. By this reaction an optically inactive body has been formed which has no action on litmus, but unites with some alkali, and absorbs oxygen with avidity, so that an alkaline glucose solution in a well-closed bottle absorbs so much oxygen that there is a considerable reduction of pressure. If a certain quantity of the neutral body is put in an alkaline copper solution, the oxide is immediately reduced to the brown (red?) suboxide. Hence, it would seem that the reducing property of glucose is to be ascribed to this neutral body entirely, which is presumably an alcohol from which are derived the various kinds of sugar.

This is not so surprising, for in 1880 Prof. H. W. Wiley showed that the reducing power bore no constant relation to the rotary power of glucose.

NO ATMOSPHERE IN THE MOON.—At a recent meeting of the Photographic Society of France, M. Janssen handed round a magnificent proof of the late partial eclipse, and said a few words upon the long-discussed question of a lunar atmosphere. In speaking upon the subject he said: "Suppose for a moment that the moon is surrounded by an atmosphere, what would be the result if we took a photographic view of it during an eclipse? The lunar disc would be sharp enough, but there would be a gradual decline in density, as in a vignetted portrait. This is exactly the contrary which took place, as the proof will show. The lunar disc is very sharp, and the negative is rather intensified near the disc, probably from refracted light." M. Janssen appears to doubt the existence of a lunar atmosphere.

LIGHT PENETRATION IN WATER.—Prof. Forel, practicing with the albumenized paper of photographers, reached the conclusion, that light cannot penetrate water to a greater depth than about 125 ft. More recently, however, some more sensitive plates have been exposed at a depth of 300 ft. under water, and the traces of light were distinctly left on the plates. Light must therefore penetrate clear water at least 300 ft., while rays so feeble as to escape detection by any known means—and yet so powerful as to exert an influence upon some forms of sub-aqueous life—may reach still greater depths.

Mining Share Market.

The stock market has not shown very much life during the week, so there have been no marked advances in any line of stock.

The following companies had cash on hand of the given amounts on the 6rst of the month: Alta, $13,417.48; Andes, $3,711.45; Benton, $6,290.33; Bnlwer Con., $36,939.35; Belle Isle, $5,278.64; Best & Belcher, $16,328.19; Bodie Con., $58,308.09; Crown Point, $22,482.58; Con. Virginia, $140,488.56; Chollar, $16,134.16; Gould & Curry, $47,623.87; Hale & Norcross, $45.393.46; Lady Washington, $1,456.54; Mono, $2,420.30; Mexican, $26,236.37; North Belle Isle, $457.77; Northern Belle, 98,659.86; Oro, $3,955.30; Ophir, $83,239.86; Occidental, $7,-178.77; Potosi, $5,354.90; Savage, $1,489 80; Sierra Nevada, $64,789.42; Standard, $58,-315.47; Tioga, $2,713.45; Utah, $1,283.44.

The following companies had indebtedness, as given: Albion, $71,544.88; Argenta, $4,-080.65; Bechtel Con., $3.095.36; California, $35,054.15; Day, $152,236.43; Grand Prize, $5,646.32; Star (indebtedness), $17,037.32; Star (old indebtedness), $38,839.84; Union Con., $9,308.37.

At the north end of the Comstock lode there are certain connections to be made for drainage and for ventilation before prospecting can be done at points of sufficient promise to attract much attention from speculators. However, when these connections are finally made, there will be a large and a fine field for the dealers. There will be crosscuts run into very interesting sections of the Mexican, the Union and the Sierra Nevada. Some of these will be at points where some ore is already known to exist. The ore deposits cut in the Sierra Nevada winzes at the time Senator Fair was in charge passed through to the eastward, and have not since been seen. These will be looked for on the levels below as soon as the north and south drifts on the 2700 level connect and afford air and facilities for prospecting. There will also be a fine field for prospecting opened when the main south drift on the 2900 level of the Union has been connected with the northwest drift of the Mexican on the same level. More will then be heard of the ore deposit left above in the winze down from the 2700 level of the Mexican.

SATURDAY night the white men employed on the Northern Pacific construction in Montana were notified by the boarding masters that on account of the increased price of beef and other supplies board would be raised 50 cents per week, viz., from $4.50 to $5. The boarding masters claim that they were losing money at the old rates. The entire force, numbering about 2,500, struck. Supervising Engineer Thielson telegraphed to the front that board would be kept at the old rates, and it is thought the men will resume work. The Chinese, numbering 5,000, are not in the strike.

PIUTES in Nevada complain that the pine nut crop was this season a very light one. Formerly pine nuts were a principal article of food with the Indians; but now when they get any they generally sell them to the whites and buy beef with the money. In this way they can get about three times as much food as the nuts would afford.

News in Brief.

EARTHQUAKE shocks continue at Panama.

THIRTY persons have been poisoned at London, Ont., from eating head cheese.

THE financial condition of Mexico is said to be even more promising than last year.

THE taxable property in Modoc county is now $1,750,000. Last year it was $1,793,270.

ONE hundred and eleven business failures occurred in the United States during the past week.

THE business of the money-order department of the post office during the last fiscal year netted the sum of $300,000.

IN Cundioimarca, South America, the President of the State and his Secretary have been assassinated.

A PARIS newspaper says it is understood that England is negotiating for the purchase of 200,000 Suez Canal delegation shares.

AT a baptizing at Canton, Ga., Sunday, the bridge fell into the river and precipitated 200 persons into the water. No lives were lost, but many legs and arms were broken.

MEXICAN advices report a threatened Indian outbreak in Sonora, and a rapid concentration of troops has been ordered from Guymas and Magdalena to meet the emergency.

THE Red Bluff *Cause* says the large planing-mill recently destroyed by fire there will be rebuilt at once. It will be a very large structure, three stories in hight, and 100x160 ft. in size.

THE officers of the Irish National Land League of America have issued a circular. It says: "The statement which has been made that the Land League no longer exists calls for an emphatic protest."

A CITIZEN of Hartford, Conn., who, 20 years ago, was worth $200,000, was three weeks ago committed to the State hospital a penniless vagabond, having brought ruin upon himself and family by drink.

HANSOM cabs, of precisely the London pattern, are to be introduced in Philadelphia by the Pennsylvania Railroad Company. Two persons may travel a mile and a half in any direction from the station for 25 cents.

THE Shasta *Courier* says: "J. Persain, of Centerville killed an immense California lion near that place Wednesday. Since the mountain fires, wild animals abound in the vicinity of Centerville, foxes, coyotes and skunks predominating."

TWO THOUSAND DOLLARS A DAY.—In our last issue, says the *Mountain Democrat*, El Dorado county, in this State, we ventured the assertion that the Alhambra claim, Kelsey township, owned by Ballard, Redd & Weatherwax, was good for $200 to $1,000 a day. Well, Reed came over on Saturday with the proceeds of two days' crushing in a small hand-mortar. Alderson melted it into two bars for transmission to the Mint, which are estimated to be worth from $4,300 to $4,500. One beautiful chispa, almost wholly free of quartz, was sold to J. E. Lyon for its weight, $44. They have pounded out about $12,000 within the last two months, and good judges estimate that there is, at least, good value for $30,000 more in sight. They have sunk one 40-ft. and one 60-ft. shaft, and have broken into the croppings for a distance of 100 ft., and all of the ore thus far exposed is of the same fabulously rich character as that already crushed.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MILL BURNED.—Calaveras *Chronicle*, October 6: We are informed that the quartz mill near Big Bar bridge, on the road to Jackson, in Amador county, was destroyed by fire last Tuesday evening. The mill has not been in operation for some time, and that the fire is the work of an incendiary there is no doubt, from what we can learn relative to the occurrence. The mill was entirely destroyed.

SPECIMENS.—Amador *Dispatch*, October 7: Mr. W. A. Nevels is again working his mine on Spanish gulch, near Middle bar. He is getting out some very fine specimens of ore that will yield as much as $1 to the pound, and much of it yield $1,000 per ton.

The Kelly mill was again set to crushing rock a few days ago. The rock from the mine is said to be looking much better than heretofore.

BUTTE.

WHISKY FLAT MINE.—Oroville *Mercury*, October 6: We hear that the Whisky flat mine on the west branch of Feather river, about a mile and a half from Magalia, owned by Ed. Felton, Charles Slocum and Dick Shipley, is now yielding well. Recently a gentleman who visited the locality saw one of the owners run out a wheelbarrow load of gravel and dump it into a sluice, and after the lighter portion of the dirt was carried off by the water he saw enough gold in the bottom of the sluice to induce him to offer $200 for what the barrow load contained. The offer was refused. The gold is coarse. Last week a nugget worth $50 was picked up in the mine. The claim is apparently an old back channel of the river.

IN GRAVEL.—The Little Butte Tunnel and Mining Co.'s tunnel into the ridge near Magalia reached the auriferous gravel of the channel last Saturday night. The company owns the ground in which is embraced the old Shepherd tunnel, which being too high to drain the channel, another adit was sought. This was found in the McKenzie ground lying south, and was purchased by the company and the tunnel just completed run, through which the mine will now be worked, as it will afford drainage for the entire claim of the company of a length of a mile and a half or two miles along the channel. From the mouth of the tunnel to the point where gravel was encountered the distance is 812 ft, and at a perpendicular depth of 189 ft. The gravel at that point is 6 to 8 ft deep and prospects encouragingly. The members of the company held a meeting on Monday evening and arranged for vigorous winter operations. Mr. McKenzie, the former owner of this portion of the ground, has worked there alone for the past 20 years, and to considerable extent prospected the channel. His former labors and results have given him great confidence in the value of the mine and the owners are sanguine in their expectation of a remunerative yield in the future. The Little Chief mine, lying upon the same ridge some 2½ or 3 miles above, are now putting in place additional pumping and hoisting machinery, and will soon be sinking again. The Dogtown, or Magalia ridge is just now attracting considerable attention, business of all kinds there is reviving, population increasing, and general thrift and prosperity foreshadowed.

CALAVERAS.

BLACK OAK.—*Mountain Echo*, October 7: The Black Oak mine is booming up and will soon take rank among the richest of the quartz mines in this district. Mr. Osborne, the owner, got some fine prospects last week. The gold is confined principally to the quartz, which is a good indication of a permanent mine.

BRIGHT PROSPECTS.—Mining interests in this section are becoming brighter every day, and a boom such as this camp has never before known for many years is inevitable. Mines are changing hands, mills are being erected, shafts sunk, tunnels run, and all kinds of mining is on the increase. This camp is destined in the near future to be the leading mining locality in the county.

The pulverizer on the Gold cliff was put in motion the other day. It worked splendidly, and judging from appearances, we should say it would crush 60 or 60 tons per day. Some little difficulty, however, has been experienced in getting the screens to work properly.

EL DORADO.

RICHNESS.—El Dorado *Republican*, October 6: During the past 2 or 3 weeks we have heard a good deal about a rich strike made by Bob Redd, over at Spanish flat, but such occurrences are so common that we paid little or no attention to it, supposing that a rich chimney had been struck and a thousand or two taken out and that that would be the last of it, but when Bob came in on Saturday evening with over 22 pounds of clean gold dust and chispas, the result of 2 day's run with a band mortar—we saw it—we confess that we rather hankered for a share in that mine. Two shafts have been sunk upon the vein to the depth of 50 or 60 ft, and very rich ore taken from both, which are some 40 ft apart. It is said that there is every indication that there is millions in it. John Ballard and Charley Weatherwax own an interest in the claim, and we understand that it is not for sale. Nothing during the "palmy days" in our mines, exceeded in amounts the richness of many of the "finds" during the past 6 months. From $5,000 to $20,000 strikes are quite common, and seem to be becoming more so; but the Bob Redd mine, Spanish flat, promises to be the best.

MONO.

BODIE.—*Free Press*, October 10: Much prospecting is being done and everything is of the most encouraging nature. When a look about is taken—a glance at other camps—it will be readily seen that Bodie is doing more work than any of them. Our bullion shipments are the largest on the coast, and while many men complain, the outlook is decidedly encouraging. The Standard, Bodie, Syndicate, Bodie Tunnel and the Noondays are turning out bullion, and it is expected that soon the Oro will also fall in line.

NEVADA.

THE NORTH WYOMING.—Nevada *Transcript*: We recently visited Woon's ravine, three-quarters of a mile west of town, and found lively mining operations going on there. The Wyoming, the Nevada City and the Chapman ranch mines are turning out the precious metal in quantities, and Messrs. Muller and Walling are busily engaged in developing their promising mine, the North Wyoming. This mine commences on the northern boundary of the Wyoming claims and runs up in the center of Woon's ravine, north, 3,000 ft, to the southern boundary of the Mount Auburn, joining on the west the Chapman ranch mine, and on the east the Merrifield lode. It crosses the Nevada City mine about 1,000 ft above where it joins the Wyoming claim. The Muller & Walling shows a well defined lode from 1 to 4 ft in thickness on the surface, and has yielded already some very rich rock. Mr. Muller has taken out from this ground some rock as early as in 1868, and it was worked with profit at Sogg's mill. It needs machinery now to pump the water and it is easy to predict that it will rank in a short time with the most prominent paying mines in the county.

PLUMAS.

THE OLD CRESCENT MINE.—Plumas *National*, October 7: Parties from below in the past week have been at Crescent, making arrangements to open the old mine and put it in good running order. Tom. Davie, who recently struck a new vein near the old hoisting works, sold his claim to Mr. Chapman, of San Francisco, who has also bought the claim of the McDonalds to the property. Davis has been appointed superintendent, and will com-

mence operations towards the full development of the mine, at once There is every reason to hope for a fine property in the old Crescent. It was the best paying quartz mine in Plumas at one time, and has not been worked to a great depth, and not thoroughly worked to the lower level. With good management and the necessary means to open it, there is no reason why a good mine should not be opened. Mr. Davis is a first-class quartz miner, and knows the mine like a book.

SAN BERNARDINO.

THE FOUR ACES MINE.—Calico *Print*: The Four Aces is situated in East Calico and joins the Cuba No. 1 on the west and the Snow Bird on the south and west. The owners are Messrs. Hendery and Cleghorn. They are working the mine themselves and have a shaft down 35 ft. The vein is almost perpendicular, dipping a little to the north and showing a ledge of 4 ft in width from the top to the bottom of the shaft. In sinking the shaft a large quantity of ore was taken out and piled up in 2 claims, and the ore pile is continually increasing as the work progresses. There is now at the top of the shaft about 15 tons of first-class ore, which, under careful assays, averages $125 to the ton. The second-class ore will have to be re-assorted when it will work at least $100 to the ton. All the ore taken out will be kept at the mine until mills are put up here or until ore buyers come to the mine and buy it for shipment. Some of the ore has been milled, returning to the owners $160 to the ton and some of the assays have run as high as 530 ounces to the ton. The indications are that this mine will become a valuable piece of property and make the owners wealthy.

THE CUBA NO. 1 MINE.—The Cuba mine is owned by Messrs. Clark, Lehman, McGilnchy and Keyes. The claim is favorably located in East Calico, and a good wagon road can easily be made to the mine at small expense. On looking over the Cuba location almost the entire surface of the claim appears covered with a conglomerate mass of calcareous tufa and porphyry carrying chlorides and horn silver. Wherever a shaft has been sunk or the surface broken, ore is visible to the eye. When the ore is first taken out it has a yellow appearance, afterwards turning black under the rays of the sun or from the action of the atmosphere. The ore lining the shaft above the cave will now be stoped out and raised to the surface and piled up to remain until it can be shipped by rail to San Francisco. There is now about 5 tons of first-class ore ready for shipment and about 25 tons of second-class ore, which will lie at the mine until facilities are such that it will justify the owners to handle it at a profit.—All the first-class ore of this mine will work $300 to the ton and the owners make it a point to not sack any that will not assay that much.

SAM HOUSTON NO. 1 MINE.—One of the most prominent prospects in Calico district is the Sam Houston No. 1 mine, owned by the Alcyone M. Co. of Los Angeles, of which Mr. E. H. Sweetzer is the superintendent. This mine was bonded last June, by Mr. Sweetzer, and a contract was immediately let for developing the mine.

SIERRA.

OOON YIELD.—*Mountain Messenger*, October 6: The Gibralter Consolidated Co., H. J. Wilsdorff, Supt., have a valuable tract of mining ground at the head of Nelson and Canyon creeks, Sierra county. Stout & Co's mine, adjoining, is paying half an ounce to the pick a day. There is an extensive gravel lead through that district. The shaft in the Gibralter is down 65 ft in mountain lava, with some pipeclay. Bedrock is 15 ft ahead. A tunnel will soon be started to tap the shaft.

THE BUNKER HILL HYDRAULIC CO., near Port Wine, are preparing for winter. Their claim pays well

THE SIERRA BUTTES QUARTZ CO.'S TUNNEL No. 9, is now in over 1,600 ft in hard blasting rock, through which the Burleigh drills push most effectively.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—*Enterprise*, Oct. 8: Making necessary repairs and extracting ore from the croppings.

MEXICAN.—Are cutting out a station at the 3000 level in the joint Ophir winze.

SIERRA NEVADA.—On the 2700 level the north lateral drift has been extended 30 ft. The south lateral drift on the same level has been extended 24 ft.

OPHIR.—Are cutting out a station at the 3000 level in joint Mexican winze. During the week 74 tons of ore have been extracted from the croppings.

UNION CON.—On the 2900 level the south drift has been extended 26 ft.

CHOLLAR.—During the 7 days ending at noon to-day 106 ft have been added to the length of the drift west from the Chollar-Norcross-Savage shaft, 2600 station, making the total distance from the shaft 406 ft. After passing through the hard belt mentioned in the report of the 30th of September, a stratum of clay, about 8 inches thick, came in, dipping about 35° from the horizon. Behind the clay was found a mixture of porphyry, clay and quartz. This material continued for 32 ft, being quite soft and was readily passed through. Behind this was another clay seam of about the same thickness as the one at the east, and carrying the same angle. After passing through the last clay, the formation was very compact, with an occasional streak of quartz through it. Yesterday (Friday) at noon a slip of black clay, 2 inches thick, came in at the bottom of the drift. This clay lies at an angle of 30° from the horizon. Under this clay is a soft mixture of clay and porphyry, with an occasional bunch of white quartz. Up to this hour (Saturday noon) the formation under this clay has changed none as the drift is driven through it. The face of the drift shows no water.

YELLOW JACKET.—During the past week the water in the mine has risen 12 inches, standing to-day about 1,151 ft above the 3000 level station. At the Winters' shaft the north lateral drift on the sage brush level is in 414 ft from the switch, having been extended 20 ft since the last weekly report, in ground composed of clay with seams of quartz. They are extracting about 20 tons of ore daily from the second, third, fifth and sixth levels. They will resume ore shipments to-morrow.

BALD MOUNTAIN DISTRICT.

ORE.—Eureka *Sentinel*, Oct. 8: Some irregular looking and very pretty gold quartz, from Bald Mountain, was on exhibition at Clay Simms' saloon yesterday. One chunk of it, as white almost as snow, is spangled all over with small particles of free gold, clearly visible to the naked eye, in the crevices of the rock. The white portion of the quartz, which looks barren, assays, also, from $40 to $50 in gold. There is one thing certain, that there is a large deposit of gold somewhere near where this surface rock was found.

BRISTOL DISTRICT.

DAY.—Pioche *Record*, Oct. 2: Last week we stated, from what we considered very good authority, that the Bistol company had made arrangements to work the Day mine ore at their mill, but Supt Terry, of the Day company, informs us there is nothing to it whatever.

CHISHOLM MINE.—Work is being shoved ahead, and a force of 30 miners are kept busily at work. It is surprising the amount of work that has been done there the past 2 months. The ledge holds its own in the different parts of the mine, and assays from $30 to $40 in silver and 25% lead. This ore is the best flux that the furnace has ever had to work with Day ore, containing everything that the furnace requires for working. One big advantage of this mine is that there are no ladders to climb. As we passed through the various drifts and tunnels, it put us in mind of the underground passages of castles in olden times, that we had read about. As work progresses into the hill, the vacant space is filled with waste, to prevent caving. Many of the large timbers put in the mine have bowed with the immense weight upon them, and if it had not been for the filling in with the waste, the top of the mountain would have caved in ere this. The cut at the west end of the mine, through into the hill 40 ft further than the old Chisholm tunnel, has not yet struck the place where the ledge turns down.

BULLION DISTRICT.

CLOSED DOWN.—Lewis *Herald*, Oct. 4: The Nutmeg mill, in Bullion district, has closed down, owing to some difficulty between the owners. For the good of the district, we hope it will be adjusted and the mill resume operations, as there has been first-class work done in it.

CAMPBELL DISTRICT.

ORE.—Lewis *Herald*, Oct. 4: Mr. James Campbell is working a force of 4 men in the Silver Slide mine, taking out ore. He has had 7 tons of second-class ore worked in the Nutmeg mill, in Bullion district, which worked $150 per ton, and has about 4 tons of first-class ore that he will ship to the Highland Chief mill, in Lewis district, which he expects will work close on to $500 per ton.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Oct. 7: The main drift on the fifth shaft level has been advanced 16 ft in promising looking ground, showing small streaks of sulphurets, from which some high assays have been obtained. Crosscut No. 1, on the same level, has been extended 11 ft, the face being entirely in quartz giving low assays. The total length of this crosscut is 124 ft. Hard rock has again been encountered in the crosscut from the main drift on the third shaft level, but 8 ft having been made during the week. The crosscut has now reached a length of 71 ft. The stopes on the 8th and 9th levels are looking well and turning out ore of an excellent grade. Stoping has been commenced on the 10th level, and the outlook is very encouraging. The daily extraction and shipment of ore amounts to about 63 tons. Mill No. 2 is running steadily and doing excellent work. The total shipments of bullion on September account were valued at $78,271. There has been but one shipment of $6,456 61 made on October account.

MOUNT DIABLO.—The east drift from bottom of winze No. 1 has advanced 7 ft, and is now in a total distance of 57 ft. The south crosscut from this winze is in 76 ft. Winze No. 2 is down 23 ft, and shows some 8 or 10 inches of $90-ore in the bottom. The east drift from the head of this winze is in 67 ft, showing a strong ledge of low-grade ore, with bunches of a better grade.

COLUMBUS CON.—The sinking of the winze from the shaft level is making good progress. The development of the ore body is showing a vein 2 ft in width, with streaks and bunches of very rich mineral.

DOWNEYVILLE DISTRICT.

BULLION.—Cor. Grantsville *Bonanza*, Oct. 4: In about a week the furnace will be running again, and then Downeyville will prove by her bullion shipments that she well deserves the name she has won, that her wonderful silver caves are no myths. What a wonderful change in 3 years! Then it took 7 windlasses and 16 men to hoist a ton of ore; the same ton can now be hoisted in 42 seconds by 2 men with the aid of steam. Downeyville has seen dark days, and we all know what hard times are, but the darkest days never found our faith waver. We knew there was a good mine here, perhaps many, and we have lived to see it verified. Rail, too, as we may say against monopolies and railroad exactions, in our hearts we must acknowledge that railroads are a blessing, and that to the Carson & Colorado Company we are indebted for much of our present fame and prosperity. Our proximity to the railroad has made it possible to get heavy freights in two days and a half, as against 7 or 10 days in the earlier years of the camp, and we gain in the difference of the cost of freight as well. Then, too, when men know that in 7 hours after getting off the cars they can be here, instead of riding in a stage for 3 days, there is no hesitation about coming to see the 2 caves, the "Silver Cave" and the "New World," which have made Downeyville famous, and few days pass without the arrival of experts and others to see for themselves that the reports, which have gone abroad, have not been exaggerated.

EUREKA DISTRICT.

NEW SHAFT.—Eureka *Sentinel*, Oct. 7: A new shaft will be started on the Clipper mine very shortly. The Clipper adjoins the Home Ticket, one of the Ruby-Dunderberg group. It was expected that connection would have been made in the Eureka tunnel, between the new shaft and the bottom east drift of the old workings, yesterday, which will give much better ventilation and enable them to follow several streaks of ore.

ORE.—Nearly 6 tons of ore were shipped to the Eureka Con. a few days ago, from the Kentuck mine, that worked $240 per ton. This mine has produced $200,000, and at one time was one of the best mines in this district..... The Mountain Boy mine, which adjoins it, has produced over $300,000, and the Rose mine, also adjoining it, and worked by the original locator, after whom it is named, has produced over $30,000. Were the necessary amount of capital employed to develop these properties, they would rank among the very best in Eureka district.

GILLIS MOUNTAIN DISTRICT.

PROGRESS.—Cor. Virginia *Enterprise*, Oct. 4: The Yellow Jacket is showing a marked improvement in quantity and quality of ore as depth is attained. The vein is unusually large for this locality.....The Hidden Treasure is a mine rich in treasure.....South Mountain is a mine of merit. The vein is large and of an even grade.....The Middlesex mine is second to none in the camp. The ore is of high grade, and the mine is rapidly improving as depth in the shaft is attained.....The Central mine (a recent location) is marvelously rich in metal from the vein's surface outcrop.....The Eermly mine, situated in the northern portion of the district, has, for many months, been a rich ore producer.....The Bay State and Empire Wave are recent locations, located upon an immense ledge, from 40 to 60 ft in width, regular in line for upwards of 400 ft, with bold outcroppings, high above the surface. "These claims consolidated" are a splendid proposition for some moneyed mining organization.....The Illinois copper mine, owned by Messrs. Furlong, Baker, White and Dunn, is of 60% richness, and the mine is attracting considerable attention from mining men.....There are other meritorious mines here in Gillis Mountain district, of which mention is deferred. Although the camp is as yet young, it is fast approaching the meridian of fame. Even now to see some of the rich ores from our little mines would do the eyes good, remove all cross-wind obstructions and extract rheumatic gout, aches and pains from the marrow bones of the Comstock millionaires.

JACK RABBIT DISTRICT.

PAY DAY.—Pioche *Record*, Oct. 2: We were shown during the week some very nice specimens of white quartz containing galena, taken from the shaft of the Pay Day mine. This is a new character of rock for Jack Rabbit district. The bottom of the shaft is now in ledge matter. At a depth of 200 ft a drift will be run. The shaft is being sunk at the rate of a foot per day.

LEWIS DISTRICT.

BETTY O'NEAL MINE.—Lewis *Herald*, Oct. 4: The water was got under control last Thursday, consequently but little work has been done on the lower level the past week. South drift keeps improving as it is advanced North drift will be pushed ahead as fast as possible, and will start to run west crosscut again. The stopes continue to yield the usual quantity of ore. The new holler is being connected and will be in operation in a few days. It is the company's intention to sink the shaft 100 ft deeper immediately. Will purchase a larger pump and put it in place as soon as possible, as it taxes the full capacity of the 4-inch cameron at present. The company will not have any more ore worked in the custom mill, but will place what ore is taken out on the dump and build a mill of their own before spring.

MORNING STAR.—Mayo incline has been extended 13 ft during the week; total depth, 270 ft; in 2½ ft of good ore. North drift, 228 feet, has reached a total length of 71 ft. This drift is in 5½ ft of ore that averages $62 per ton in gold and $21 per ton in silver. Everything in and about the mine working and looking well. Mr. T. O. Morgan, the gentlemanly superintendent, informs us he will build a mill and have it in operation before spring. The road is finished within 100 ft of the summit, and will be completed by next week.

PIOCHE DISTRICT.

RAYMOND & ELY.—Pioche *Record*, Oct. 2: Ore from the black ledge of the Raymond & Ely mine, which was sorted and thrown out on the dump as waste, proves to be pretty valuable waste rock. The other day Mr. J. V. Keeley picked up a chunk of waste rock and had it assayed. It showed 120 odd ounces in silver and 30% lead. Certainly not a bad showing for waste rock.

SAFFORD DISTRICT.

ORE SHIPMENT.—*Silver State*, Oct. 8: Ross & Co., owners of the Contention mine, in Safford district, have shipped a carload of ore from that mine to Salt Lake. Assays of the ore indicate that it will work over $300 per ton.

SANTA FE DISTRICT.

COPPER.—Cor. Virginia *Enterprise*, Oct. 2: Colone Burdick's copper mine, of Santa Fe district, is showing up most encouragingly as work progresses.

TUSCARORA DISTRICT.

BULLION.—*Times-Review*, October 7: During the month of September just past, there was shipped from this place bullion to the value of $40,384 40, principally from the Navajo mine. During the present month the shipments from the Navajo and Independence mines will not fall far below $100,000.

ARIZONA.

DEVELOPING.—*Arizona Miner*, Oct. 6: The Occident mine is developing richer and larger at every stroke of the hammer, and gentlemen well acquainted with the Peck are of the opinion that the Occidental equals the Peck when it was turning out bullion in miraculous quantities. We are pleased to hear such good reports from this property, as the owners are liberal, enterprising gentlemen who have done much for this county, and deserve good returns.

TOMBSTONE.—*Republican*, Oct. 7: Work is proceeding with the usual vigor. Prospect work is being extensively done, and development is progressing with more vigor and rapidity than ever known in the camp. The great producing mines are working along as usual, and giving to the wealth of the world their many thousands of dollars weekly. Contention hill has got nothing but good news to report. The Contention's bullion output for the month of September was over $150,000. The Grand Central yielded over $100,000; the Head Center exceeded $25,000. This is a general increase all around. The T. M. & M. Co. has not as yet received full returns for the month, but we have no doubt that it will be flattering when received. The successful experiment of using manganese for flux, which has been tried by the T. M. & M. Co. at their furnace in Charleston, is of vast interest to the camp. The quantity of manganese ore in the western portion of the district is greater than is generally supposed, and, as it all contains more or less silver, the importance of the experiment can be estimated.

EMPIRE DISTRICT.—Cor. Tombstone *Republican*, Oct. 6: Ever since the famous Total Wreck demonstrated to the world the wonderful richness and extent of its ore deposits, the attention of mining men has been directed to our district, with the firm belief that other bonanzas would be uncovered. The Total Wreck mill is completed, and is fully the equal of any in the Territory. It now awaits only the completion of arrangements for water supply, when the bullion stream will commence to flow and advertise to the world our resources. The purchase price of the Forty-Niner mine, $50,000, was paid last Saturday. It was bonded some months ago, since which time work has been steadily pushed. It is opened to a depth of 115 ft, all in ore, and a crosscut on the 93 level shows a ledge 20 ft in width. Drifts from the same level show a large body of high-grade, free-milling ore, fully equal to that of the Total Wreck. The Michigan Boy has been developed to a depth of 50 ft, and is regarded as a property of great promise. The town is growing steadily, and when the mill starts up a grand rush is expected.

MYERS DISTRICT.—*Arizona Citizen*, Oct. 2: Mr. M. C. Campbell arrived from the Myers district Saturday, and reports a big strike at the depth of 100 ft in the C. & C. mine. From the bottom of the shaft, at the depth given, a drift of 20 ft reached and cut the ledge which, so far as opened, shows over 2 ft of solid silver-glance ore. The strike is regarded as a remarkable one, and one that has enhanced the value of the mine much. The vein, so far as opened, averages over $100 to the ton.

THE smelter at Benson was fired up for the first time Thursday. It was feared for a while that sufficient water could not be had at the furnace, as a well 100 ft in depth failed to reveal any. A second well, of similar depth, was abandoned with like results, but a third well, at a depth of 35 ft, yielded abundantly. The first well was then continued to a depth of 140 ft and a tunnel run from it to connect with well No. 2, which had been sunk lower down on the mesa, thus giving the works a full supply.

COLORADO.

WILLIAMS' FORK—GRAND COUNTY.—*Register-Call*, Oct. 6: Geo. Wir z, of Nevadaville, who is interested in several leading mines in the new mining camp on Williams' Fork, Grand county, reached Novadaville last evening.... The Ready Cash, property of Igo, Wilson & Co., has been leased and bonded to Williams & Co. for a period of two years, who are working the property with a view to active development. A tunnel has been driven on the Ready Cash 260 ft in length.....E. H. Moran & Co. are still driving a crosscut to intersect the Iron Brigade vein. They have yet quite a distance to drive before reaching the vein.....The Silver Moon is a recent discovery made on the same mountain where the New Florence and Bobtail are situated. E. H. Moran and Mr. Marsh are the owners. This is considered one of the best finds made this season. The ore prospects well in silver.... Three miles below these mines Capt. William Z. Cozens is developing the Yellow Jacket mine with profitable and flattering results. A quantity of ore from the Yellow Jacket has been shipped to Georgetown for sampling and assay.....The miners feel the necessity of a good wagon road. At the present time their only inlet and outlet is over a trail. Steps are being taken for the building of a road.....The miners feel sanguine that, by another season, the mines of the camp will give a steady output of ore, and anticipate a lively season in mining.

IDAHO.

MONARCH.—Ketchum *Keystone*, Oct. 2: The Monarch mine, at Atlanta, will have its new hoisting works in operation before many days. The Monarch is one of the very richest properties in Alturas county, and has already yielded its thousands. The mine has heretofore been principally worked by tunnels, and the new hoisting machinery is for the purpose of working from a shaft.

BULLION SHIPMENTS.—Eight 8-yoke bull teams went out Sunday loaded with 70,000 lbs of bullion from the Philadelphia smelters. Fifteen thousand pounds of bullion from the Philadelphia smelters went out on horse teams yesterday.

WILL MAKE A GOOD RUN.—Col. Miller, manager of the Philadelphia smelting works, is purchasing ores from all parts of the country, as well as making regular shipments from the company's mines, and is confident of making a long and successful run, so we are informed.

THE DAVITT.—We learn from Mr. Flynn, the owner, that an increased force will soon be employed in taking ore from the two tunnels now opened on the ledge, and frequent shipments will be made to the Ketchum smelting works, as long as practicable this year. Mr. Flynn has already made an opening shipment from the Davitt of 25 tons.

THE SILVER KING.—The Silver King mine, located 4 miles above Sawtooth city, and formerly spoken of as the "Kelley strike," is developing enormous riches. The ledge, as it now appears, has a total width of 15 ft, and, within this limit, little or no waste matter is found. Operations are exclusively in pay rock, and, instead of securing a small quantity of ore from a vast amount of barren ledge matter, the operation is vice versa, and but little of the whole amount handled, is necessarily ejected.

MONTANA.

MINING SALE.—Helena *Independent*, October 7: The recent sale of a portion of the Wright & Edwards mine at Baker for the Snug sum of $20,000 has created quite a boom in the mining interests of that camp. The purchase was made by the Glendevin Smelting and Mining Co. by the advice of Prof. Foss, who, until quite recently, has had the entire management of the smelter. This sale would seem to indicate considerable faith in the mineral deposit of that section.

LARGE BULLION SHIPMENT.—*Inter-Mountain*, October 7: In the express office in this city last evening was seen the gratifying spectacle of 38 bars of bullion, received in one day for shipment. Of this number 11 bars bore the Alice stamp; 13 were from the Lexington mill, 4 were from the Silver Bow mill and the remaining 6 from the Moulton. It is not too high an estimate to say that this bullion was worth $40,000. This, of course, is not an average daily shipment, but is extremely gratifying when the published weekly shipments do not often exceed $60,000, and occasionally do not reach that sum.

HOPE.—*Inter-Mountain*, October 2: The Hope Mining Co., Philipsburg, has declared a quarterly dividend of $3 per share, or $24,000, payable to-day at St. Louis, total amount declared to date, $60,000.....A two-foot vein of good ore has recently been opened in the Moody & Sankey. This location adjoins the Gold Flint in Independence district. Samples from mines there assay from 200 to 500 ounces.....Thunderbolt mountain quartz mines are coming to the front, and if the report of rich gold and silver-bearing ore discovered are not exaggerated, Deer Lodge county has some very valuable quartz property.....Mr. J. B. Orr reports the placers of Dry gulch still yielding handsomely. They pay $35 or $40 per day, to the man. Three additional men were put to work this morning. The water supply holds out and operations will continue until cold weather.

NEW MEXICO.

FROM THE PALOMAS DISTRICT.—*New Mexican Mining World*, Oct. 6: The developments which have been made during the past year have shown the mineral belt of the Black range to be continuous from 10 miles north of Chloride to 10 miles south; and ores of copper, gold and silver are distributed lavishly throughout the whole distance. The new discoveries in the copper belt of the Livingston Con. mines, bringing a property to the front as a sure producer of copper, which, heretofore, has been looked upon as a property of great promise. The Copper Bell is about 6 miles south of Chloride. The vein is 5 ft in width and contains the carbonates and oxides of copper, as well as the metal in its native form in kidney distributed through the vein; wall rock being mineralized some distance from the vein. This property is worked by a slope following the vein, which dips westerly about 15° from the horizon, and its owner, Mr. Sam Foster, is pushing developments, and expects to have the mines in a regular producing condition soon.

THE MOGOLLON DISTRICT.—At Silver creek the Gold, Blue Bird and Red Bird are throwing up ore that is very rich, and the arastra here is running daily on the same. It is said that the California syndicate will soon commence afresh on their mining properties in the vicinity, and Johnson & Ebertie will soon put a force of men at the head of drills in their mines.

MINERAL CREEK.—Senator John A. Miller is forming a company in Iowa to work his rich leads on this creek, and ere long, will make his tunnels longer and shafts deeper.

THE Cooney M. Co. is the company now on this creek at the present writing, and is making matters in general extremely lively. In and about the bar Supt. Jewett has 45 men at work in and about the mine. The air-pump machinery is en route for the mine, and when in place more men will be added to the pay-roll. Lots of men are in the mountains burning charcoal, hewing timbers and quarrying rock for the mines and houses of various kinds. Last Saturday the miners threw down 50 tons of ore from the upper tunnel, and $1,000 has been paid aloue to make a place for these huge dumps to be landed from the tunnels. In the Socorro bank the company has a special deposit of $44,000, to be used exclusively for mine-developing purposes.

SOCORRO COUNTY.—F. A. Thompson, of Socorro, and others, have bonded the following mines: Robert Ingersol, Last Chance, Ninety-nine, Eighty-two, Jockey Club and Hiawatha, in the Bromido districts, from L. J. McCullugh for $80,000.

WORK is plentiful for miners about Socorro. So much assessment work is being done that good workmen are scarce. Seventy-five men were wanted for the Torrence, but could not easily be found. There is a difficulty in supplying the proper number of hands at the smelter.

THE tramway of the lower tunnel of the Cooney mine has been completed. Double shifts are now pushing the work towards the main lead. Last week the workmen shot down 1,000 lbs of silver glance ore at one blast, which assays $1,000 to the ton. The 5 mule teams that brought in the ventilating machinery have started back to Socorro loaded with 7,239 lbs of ore from the Cooney mine. This is rushing it in earnest.

BURRO MOUNTAINS.—*New Southwest*, Oct. 2: They are now having a genuine boom in this camp. The Valverde Co. turns out 40,000 lbs copper this week, and starts up another furnace Monday. The ore output is increasing daily, and the quality still improving.

THE Pittsburg mine now shows 5 ft solid copper ore in the bottom of the shaft, and is getting better every foot.

THE St. Louis is yielding up her usual quota, there being no special change since last week.

THE Queen City smelter started up Tuesday morning with perfect success—making a good run of copper the first day—from furnace No. 1 and No. 2, is being made ready for business. The company has also on the ground a Pacific water-jacket furnace, built by Rankin, Brayton & Co., which they will put in operation as soon as a supply of water can be brought in.

THE Oak Grove works are located in a beautiful natural park, in the midst of native evergreens, and is just at the foot of the Burro mountains, from which the company mine the ores for the smelter. So far, they are only working the Mary mine to any extent, but the company has purchased the famous Burro Chief group of mines, located near their extensive works, and, with this purchase, have undoubtedly secured for themselves one of the very finest mining proper ies to be found in this Territory. The present output is sufficient to supply their smelter with good ore, and can be doubled by increasing their force of miners.

MODEL MINING REPORT.—If true, as said, that brevity is the soul of wit, then the following mining report is the wittiest ever written. It emanates from Boh Howland, and is the result of an examination of an Arizona mine; "I, E. James, Esq., Dear Sir—Read at your leisure the following report: I find no quartz, no porphyry, no ore." Respectfully,

R. M. HOWLAND.

MATT. CANAVAN has placed a lien upon the property of the New York Mining Co. on the Comstock, to secure $2,703 due him for salary as superintendent, from October 18, 1881, to October 18, 1882. Roger Sheehan placed a lien upon the same property to secure $1,080, due him as watchman.

THE Utah paid ont the other day for labor $3,932.50. The Union paid $9,643.73, and the Consolidated Virginia, California and C. C. Companies paid $13,014.50.

A NUMBER of Piutes are employed at the marsh of the Nevada Salt and Borax Company, out on the Carson and Colorado railroad.

Manganese for Flux in Smelting.

We have mentioned in theee reports, at different timee within the last month, says the Tomhetone *Republican*, the problem of utilizing the manganese of this dietrict as a flux for smelting the tailings that have accumulated at the Tomhstone company'a mille, at Charleston, since they firet commenced work. Any process hy which this clase of ores can be eucceesfully treated, at small coet, opens up an entirely new future for this district. The lime fields of Tomhetone comprise a large porportion of tbe entire mineral-hearing area, and nine-tenths of the oree contained therein are heavily impregnated with the hlack oxide of manganeee, iron and silver. Of the mines upon which a large amount of development has heen done are the Stonewall, Contact, Eagle, Randolph, Wedge, Prompter, Lncky Cuss, Lnck Sure, Bunker Hill, Rattlesnake, Green Cloud, and othere of lesser note. Theee ores carry from 10 to 200 ounces of silver to the ton. Stonewall ore has heen euccessfnlly treated hy amalgamation after first roseting the ores. Anyone at all familiar with the coet of treating ore hy dry cruehing, roasting and amalgamation, knowe that nothing hut a high-grade ore will pay.

On Thursday of last week the furnace at tbe Gird mill, Charleston, was fired up and everything got in ordar, eo that on Monday morning of this week it was ready to start upon a eteady run. From Monday morning up to Thureday evening the furnace ran at about one-half its capscity, having many etoppage e. consequent upon raw men in every department outside the superintendent and one other man. Then there was the proper admixture of flux to he determined, which was no small item itself. Manganeee was to be enhstituted for iron, which was an experiment hefore untried in smelting silver oree, which wae looked upon as one of the principal factore in the euccess of the enterprise.

Fortunately for Tombetone, Mesers. Rhodes and Anstin, the former assistant euperintendent of the company and the latter euperintendent of the mille and emelter, were correct in their estimate of the action of manganeee as a flnx, and the trial was a perfect euccess in every eenee of the word. The slag from the furnace, when everytbing ran emoothly, only gave one-half an ounce of silver to the ton, and when clogged hy the inefficiency of the feeders, two ouncee. The hullion aseayed $400 per ton in silver and two onncee in gold. This makes the hullion, counting the unrefined lead at four cents per pound, worth $520 per ton. Tbeir output from Monday morning up to Thnrsday evening, running at half capacity, was 10 tone of hullion, having a grose valne of $5,200.

This euccees opene up a far hrighter future for the district than any event eince the successful dropping of the first etamps in the Gird and Contention mills. We have botb carbonatee of lead and manganese in almoet houndlese profusion, with large amounte of very rich chloride and horn silver ores, which can be more economically treated hy smelting than hy any other process, all other things heing equal. The rich Way Up, Vizina, Ingereoll, Lnck Sure, Little Devil, Bonanza and Winfield oree are of this type. The last dollar in value of euch ores can he taken out by smelting, where the fluxes are so perfect as here.

Mechanics' Fair Premiums.

The Board of Managers of the Mechanics' Institute met and annonnced the following additional awards to exhihitore:

V. S. W. Parkhurst—Best display of scales, silver medal.
W. T. Garratt—Display of hells, silver medal.
H. D. Ranlett—Display of copper ore, diploma.
W. H. Smythe—Mechanical drawing, diploma.
Smythe & Watson—Tree feller and log saw, silver medal.
George Ball & Co.—Portable sawmill, bronze medal.
R. Walkingshaw—Improved port window, diploma.
Adams & Carter—Improved tappet for quartz mills, bronze medal.
F. Webb & Co.—Rubber stamp, diploma.
Truman S. Clark & Co.—Folding bedsteads, bronze medal.
John Driver—Mortising machine, diploma.
Henry Doyle & Co.—Display of Clark's O. N. T. thread, silver medal.
Pupils of tbe Public Evening Schools—Drawings, silver medal.
California Powder Works—Sporting powder, silver medal.
J. S. Bennett—Set of hand-made furniture, bronze medal.
W. T. Coleman & Co.—Royal baking powder, silver medal.
Will & Fink—California made combs, bronze medal.
Misses Dietz—Patent dust-pan and crumb receiver, bronze medal.
Harriet F. Baily—Paper sculpture, diploma.
H. Slocomb & Co.—Dipple drip lubricator, diploma.
H. Liebes—Carriage robes, bronze medal; colored furs, diploma; sheepskin mats, bronze medal.
A. F. Merriman & Son—Dental toilet articles, diploma.
Parisian Polish Company—Polish, diploma.
Arpad Haraszthy & Co.—California champagnes, gold medal.
J. Gundlach & Co.—California wines, gold medal.
J. T. Cutting & Co.—Falk's Milwaukee beer, diploma.
J. Hunt—Blackberry cordial, diploma; Peruvian stomach bitters, diploma; Burnell's Albion ale, diploma.
John Rosch—Mathematical and surveying instruments, silver medal.
P. B. West—Optical apparatus, bronze medal.
Woolhouse Bros.—Gas machine, bronze medal.
J. H. W. Riley—Caligraph, diploma.

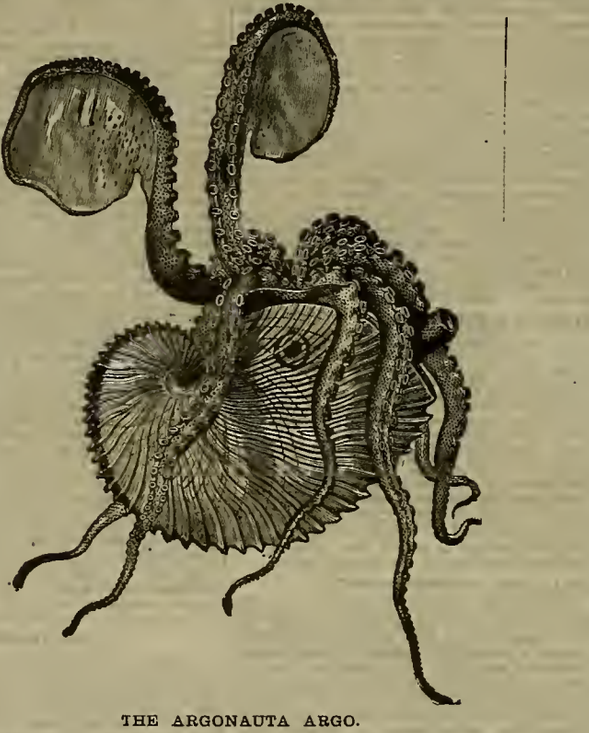
Clase No. 2, embracing hydraulic machinery, and the cash premiume, are now all that remain to he announced.

PIRU MINING DISTRICT.—From a letter received from the Piru district, in the San Emigdio mountains, about 40 miles south of Bakerefield, we take the following iteme: The mines here are heing developed elowly hut snrely, the large veins showing a good class of argentiferoue ore ae they go down. Messrs. Fitzgerald and Paileley are taking ont some very good gold ore from a emall vein, averaging eight inchea wide, and will atart up their arastrae hy the 1et of Octoher.—*Kern Californian.*

A Curious Marine Animal.

We give our readers on this page a glimpse at a peculiar denizen of the deep known as the argonant. Tbe argonaut is a molluek of the class known as cephalopode. The cephalopoda, or cepalopods, (from two Greek worde meaning "bead" and the "foot," hecauee the "arms" or "feet" eurround the mouth,) are the higheet class of the molluscs, and inclnde the cuttle-fishes, nautili, argonauts, ammonitee etc., all marine and carnivoroue, and all laterally symmetrical, having a ebell neually etraight, hut sometimes coiled in a vertical plane. Thenautilli and argonauts alone have external shelle, though many extinct epecies had them; but the other living speciee have generally an internal ehell, of which "cuttle-fieh hone" affords an example. The cephalopode have muecular arme or tentaclea, ueed in preheneion and locomotion; many have fins, and all have the power of locomotion by forcihly expelling water from tbe gill-ohamher. They generally have two large eyes, ear cavities, each containing an otolite, two jaws, and a fleshy, epinoue tongue. The nervone eyetem is well developed. The hrain forms a ring encircling the aesophagus. The gille are either two or four in number, placed in a chamher into which water ie admitted by a elit, and from whicb it is expelled through a "siphon" or "funnel."

The argonauts (*Argonauta*) sre a genns of mollusks of the class cephalopoda; ie commonly called "psper nautilue." The latter name is derived from the fragile nature of the hoat-like ehell in which the argonaut floats on the snrface of tranquil eeas. The ehell is not chambered like that of the true nautilus, hut has one epiral cavity, into which the animal can retire and he completely hidden. There is no mnecnlar attachment of this animal to the ehell, which is said to he pecnliar to the female, who uses it for incuhation, as a nest. Several speciea are known. They have eight arme, two of which are expanded into broad membranoua disce, which were formerly believed to he aails, and the other arma were regarded as oars; bnt, though the fable ie perpétuated by the poets, it has long been known that the animal really propells itself hy ejecting water from ite fnnnel. When it desires it folds ite arms, retiree within ita shell, and ainks to the hottom.



THE ARGONAUTA ARGO.

The argonaut shown in the engraving is the female, and is qnite a gorgeous animal. The male is an ineignificant little chap. It ie said hy the naturaliet that the female when ehe becomes lonely takea up the little male for a ride in her ehip, and when ehe tires of his society she pitches him overboard again to ehift for himself in the mighty deep.

LIME.—Col. A. H. Miller, one of the managera of the Hydro-Carhon Lime Works, at Colton, informs a Los Angelee exchange that the firee were etarted recently in this important estahlishment, and that lime will be in constant supply thie week and afterward. Another kiln will he made at once. The company nse petrolenm aa fuel, and ia hnrning the fine oils of the Puente wells, of Messrs. Chandler, Rowland, Lacy and Johneon. This is an important movement in which California oil makes California lime, and completee the round of home indnetry.

Nostrums Exposed.

The Sophomore class of Michigan State Agricultural College have been making good nee of their leisure time in the laboratory hy analyzing the varione noetrnme which have flooded the markete of that state, and of which other statee have had their full ehare. Judging from the enormoue enms which muet be paid for advertising them, the eale of these worthleee enhetances constitutee one of the greatest eystems of ewindling in the whole country, and one of the best things chemists can do is to expoee them, as the studente of the Michigan Agricultural College have done—the reenlte of whose nsefnl work we copy from the *College Speculum*, the real cost of the article and how it is made heing given, and ite market price.

1. Coaline.—Eight ouncee of sal soda (carhonate of eoda) in a gallon of water, with a few drops of nitro-henzol to give it an agreeahle odor. Coste 3 cents a gallon; retail price 40 cents.

2. Silver Plating Fluid.—An ounce vial of eolution of nitrate of mercnry, which will form a temporary silver coating when rubhed on hrass, copper or eilver, which speedily tarnishes when expoeed to the air. Coet 3 cts.; retail price 50 cents.

3. Nickel plating fluid is the same as 2, except that a little nitrate of copper and nitrate of nickel are added to the eolution of nitrate of mercury. Coet 3 cents; retail price 50 to 75 cents.

4. Fire teet powdere, to prevent explosions in kerosene lamps, the breaking of lampe and chimneys, and the danger of hurning from the nse of low-grade oil. Theee are pill-hoxes containing one or two ounce of common salt, colored with aniline red. Coet 1 cent a box; retail price 60 cente, or two for a dollar.

5. Fire proof powder from Wieconsin is waterlime. Cost ½ cent; retail price not known.

6. Silver polish. Pill-box filled with waterlime. Coet ½ cent; retail price 25 cente.

Thia is only a part of the nostrume examined hy the clase in chemical analyaie, and other snbatances, await their turn.

A Losing Mine.

In central Arizona the old Vulture mine, in Maricopa county, eeema to he rnnning to the had very fast. The following atatement ehowe its prodnct and expenece for the month of August:

General expenses	$ 900.45
Exchange	81.60
Water service	2,240 51
Mine	6,913 46
Mill	7,173.31
Dead work	1,500.00
Total	$18,909 33
Product, 704½ ounces bullion	11,115.81
Deficit	$7,693.52

Ruuning time, 25 daya and 20 hours; ore and waste crushed, 5,394 tons. Average prodnct per ton, $2.02, nearly. Assay of tailinga ahow loss for the month, on an average, of $1.52 per ton, of which amalgam loss was 51 cente, the halance heing snlphurets.—*Tombstone Epitaph.*

A MINE AS IS A MINE.—Up in Shasta, Cal., they have a mine called the Afterthought, which is claimed to contain, mixed together in grand confnsion, gold, silver, copper, antimony, zinc, snlphnr, cinnahar, iron, graphite, etc. The "etc." prohably standa for indigo, soap, borax and ivory hlack.—*Virginia Enterprise.*

Old California Mining Camps.

James Rule, the well-known mining man and mining Superintendent of this city, has just returned from an extended trip among the old mining camps of Tnolumne, Amador, Calaverae and other conntiee of the southern part of California. He vieited a great number of the old-time rich gulchee and flats. Years ago, when he was familiar with them, theee placee ewarmed with miners. Men were taking out fortnnes with eluicee and rockere. Nearly all the largest and heet diggings were emall towns that were bumming with all the life and most of the vices of great ciitiee. Now he finds the majority of these towns thinge of the past. Some few still linger along, hut of the greater part, not a veetige remains.

Where formerly were eeen throngs of men delving in the gravel hanks of flat and canyon, with hlood at fever heat and braine on fire with the excitement of a succeeeful eearch for the precious yellow metal, he now finde eettlements of plodding, etolid cultivators of the soil. The old canyone and flats—every epot to which water can he hronght—are now occupied by men who have no thought of mining for gold. These men are nearly all Italiane. They are from the monntainous parte of Italy, and ranked se peasants in their own country. Their chanties are found along the canyone, far np into the mountain. They take poeeeeeion of the old worked-out flate on these cayons for use as gardens, and in places have planted vines on the elopes of the hille, as far up as they have been able to carry water.

The people live much the same ae they did in their own country. The greater part of their subsistence comes from their gardene and vineyards. Inetead of tea or coffee, the majority drink wine of their own making. The men scout out down the mountains, 20 or 30 milee to the nearest towns, with pack animals loaded with fruit and vegetahles. In thie way they get flour and eome other neceeearies they cannot produce on their own ground.

Among theee people an American feels loet. Few of them speak English, and a newspaper of any kind is not seen in monthe. Most of the houeee are mere hute, and the "explorer" finde it a difficult matter to procnre lodginge for even a single night. Although they live on next to nothing, none of them appear to he rich in anything except children. These ahound. Half a dozen children are seen tumhling about the floor of nearly every cahin, and many of these floors are earth. In most placee there are eeen together from two to five cahine, hut far up in the monntaine are often seen eingle huts that are milee apart.

On eome of the gulches there ie a sprinkling of Chineee, and on some of the larger flats, at and ahout the mouthe of tbe canyone, are found a few Americans or men of other nationalities, besides thoee of Italian origin. Aleo in a few localitiee are found in their lone cabine, old white-headed minere of the daye of "'49." These men search for pockets in quartz veins, pan and crevice ahout in epote known to have been rich in the early timee, thus procuring enough gold duet to purchaee the few articlee they require.

About Columbia, Sonora and a few other towns, there is etill considerahle mining, and the surroundinge have something of the look of old timee. Men who left theee old mining campe from 15 to 20 years ago, would now feel utterly loet and disgusted ehould they begin explorations for the rediscovery of their old digginge.—*Virginia Enterprise.*

MINING UNDER DIFFICULTIES.—Through hreaksge wagons, and accidents and delays to the pack train, esye the Inyo *Independent*, the new castings and machinery for the Inyo Consolidated company's hig mill at Surprise canyon were delayed, and the repaire were not completed nntil the 10th of Septemher. The mill wae to etart np the following day in perfect shape. The company hae expended nearly $5,000 in this work, and has now as complete reduction worka as can be found in the State. The minee have developed eo well, that with the 500 tona of ore now out, Superintendent Phehy thinks he can run over 1,000 tons—the best run ever made in the camp. In ahout five months from this time, the Carson and Colorado railroad will ohviate all the difficultiea now experienced in this region in getting in heavy castinge and machinery. Many milla will he hnilt in the region into which thie road is ahout to enter. Where arastraa are now being run, stamps will preeently be hammering away. At Bishop creek one mining company, the Sacramento, is now running five arastras.

WORKING A GOLD MINE FORTY YEARS.—There is a gentleman living in Coweta county, Ga., who haa heen working a gold mine 40 years, and for the last three yeare without any other hnainees, and who haa carried out all the dirt from hia pits in a sack on hie hack. One of his pits, he aaye, is 65 ft. deep. Although he has found gold, he has never realized one dime of profit from all his labor, but ie yet at work, and sure of success. The eame gentleman drove a yoke of steers from here to the State of Arkaneas to look out the country, epent a few monthe looking, has worn out his wagon, had a new one hnilt, was not satisfied and drove the same yoke of eteere hack to Cowsta.—*Atlanta Constitution.*

THE number of yellow fever casea at Brownsville eince the beginning of the epidemic is 1,900. The number of deathe is 107.

The Engineer.

Defective Brick Piers.

The committee of architects appointed by Kraft, Holmes & Co., to investigate the fall of the building lately occupied by them, in St. Louis, have made their report. It is made on calculations based on standard authorities. No defects were found, except in the basement piers.

The brick piers in the basement will have to carry the load of all the floors and roof added. This will be 74,100x5, equal to 370 500, to which add 7,410, and will have 377,910 lbs., which is 189 tons.

The dimension of the brick piers being one foot ten inches by two feet five inches, will give four and one-half square feet as the area of each pier. The average crushing load of first-class hard brickwork laid in cement mortar is about 60 tons per square foot; and again, taking one-sixth as a factor of safety, we will have 10 tons per square foot as the safe load; and if each pier has 4½ square feet, it will give 45 tons as the safe load to be imposed upon piers of this size.

It will be seen from this that 189 tons was four and one-quarter times as great as the pier was reasonably able to carry. It is therefore evident that the brick piers, being the weakest part of the structure, had to give way first, and they caused the disaster.

While the above calculations are based upon brick piers of the very best quality of workmanship and materials, the piers in this building were not a fair average of work.

Steam on Street Cars.—After the most faithful efforts of the managers of the street cars in Paris to substitute steam power for horses, they have given up the job. For five years they have used steam, during which period, they have tried 21 different forms of engines. The companies now discard steam, and return to horse flesh as, on the whole, the safest, most economical, and most satisfactory. It would seem as if the experience ought to be of value to inventors; that they can and will ultimately overcome every difficulty, there can be no doubt. Who will win the prize by the invention of a steam street car that will successfully compete with animals?

Railroad building is going on at a rapid rate all over the country. During the month just closed it is estimated that 1,209 miles of track were laid, Iowa leading the States with 154 miles, and California being represented by the respectable amount of 89 miles. The total amount of track laid this year is 8,075 miles—a greater number of miles laid than in any previous nine months. It has been predicted by many critics of our country that the railroad-building craze would end in disaster; but thus far we seem to have been saved from the danger of a crash like that of 1873.

The Carrying Capacity of Freight Cars.—It is only a few years since freight cars were allowed to be loaded with more than 10 tons. Now but few eight-wheel cars are built with a carrying capacity of less than 20 tons. The advantages and economies secured by increased capacity are such that a committee of the Master Car Builders' Association has recommended the building of 25 or 30-ton test cars, believing that freight can be carried in 30-ton cars with as much safety and with greater economy than in cars of less capacity.

The Largest Wrought-Iron Columns.—The wrought-iron columns made by the Phœnix Iron Works for the Albany bridge are said to be the largest ever made. The length of each is 53 ft. 3⅜ inches. Each is composed of eight segments, the iron of which is 1 9 16 inches thick. Each column requires 894 steel rivets, and the weight complete is 18,806 lbs. The square inches of section are 104. The eight columns, therefore, contain 150,448 lbs. of metal and 7,152 rivets.

Over 400 Miles a Day.—The Union steamer *Alaska* has again beaten her best westward record. She left Liverpool June 17th, and Queenstown at noon the next day. She arrived at Sandy Hook at 9:45 on the morning of the 25th, her corrected time for the run being 7 days, 1 hour, 50 minutes. On the 22d the distance run was 430 miles. The average for the trip was over 400 miles a day.

Pressure in Punching.—The pressure required to punch a round hole, one inch in diameter, through one inch wrought iron, will average about 150,000 lbs. It will, of course, vary somewhat, according to the character of the iron operated upon and the construction of the punch and die.

The Widest Gauge Railway.—Washington Territory boasts the widest gauge railway yet reported. It is an 8 ft. gauge logging road, running back from Skagit river. The rails are wood, 8 by 8 inches. The cars are large, and are carried on 12 wheels, of 9 inch face, with double flanges.

Exhaust.—The exhaust of an engine may be deadened by running it through a large box filled with perforated heads, or with ordinary pebbles all of one size. If the box is large there will be no back pressure made. Another way is to utilize the exhaust to heat the feed water.

Useful Information.

Weales' Description of the Screw.

A screw is a spiral groove or thread winding round a cylinder so as to cut all the lines drawn on its surface, parallel to its axis at the same angle. The spiral may be either on the convex or concave surface of the cylinder, and it is called accordingly, either the screw or the nut. The screw can hardly be called a simple machine, because it is never used without a lever or wrench to move it home; and then it becomes an engine of amazing power and utility, in pressing together substances that have little cohesion, or in raising to short heights ponderous bodies. The smith, the carpenter, the printer and the packer all use screws in their respective occupations. Bales of wool, cotton, hay, etc., may be compressed by means of a screw into packages, the specific gravity of which shall be much heavier than an equal volume of water. Moreover, many of our domestic operations are performed by means of presses or screws, as the making of sugar, oil and wine. The screw possesses one great advantage over the inclined plane, from which its principle of action may be said to be derived. The great attrition or friction which takes place in the screw is useful in retaining it in any state to which it has once been brought, and continuing the effect after the power has been removed. It is thus the cabinet maker's cramp, the smith's vice, and all these instruments made by mathematical instrument makers, in which screws act, can be employed with certainty. Screws are made with threads of various forms; some have sharp, others square or round threads.

How to Make the Phosphorus Metals.—For the preparation of phosphorus compounds of metals, for example, phosphor-copper, Dr. H. Swarz gives in the *Industrie-blatter* the following directions: A mixture of bone ash, silica and carbon is placed in a crucible, and upon it a layer of granulated copper, which is in turn covered with the above mixture. The lid of the crucible is luted on. To make it melt more easily, some carbonate of soda and glass may be added, or a mixture of pulverized milk-glass with charcoal and powdered coke is used for lining and covering it. Take, for example, 14 parts of silica, 18 parts of bone ash, and 4 parts of powdered carbon. This is mixed with 4 parts of soda and 4 parts of powdered glass, stirred up with a little gum water, and used to line the crucible. When this is dry, the copper is put in and covered with the same mass, and the whole melted at a bright red heat. The copper obtained flows well, and has a reddish-grey color. It contains from 0.50% to 0.51% of phosphorus. The simplest method for introducing phosphorus into bronze, says the *Metalworker*, is to stick a bar of the phosphorus into a tube of pinchbeck, one end of which is hammered together and closed tightly. After the phosphorus is put in, the other end is closed too. When the metal, which contains 32 parts of copper to 5 of zinc and 1 of tin, is melted, the tube charged with the phosphorus is pushed down in it to the bottom of the crucible by means of a bent tongs. The stick of phosphorus must always be kept under water until it is about to go into the pinchbeck tube, when it must be carefully dried, as the presence of any moisture would be sure to cause the metal to spurt or fly about.

To Make a Good Sand Paper.—As in cleaning woodwork, particularly pine and other soft woods, one process is found to answer better than another, we may describe the manner of manufacturing a stone paper, which, in some cases, will be preferred to sand paper, as it produces a good face and is less liable to scratch the work. Smooth on both sides, with pumice stone, any good tough paper, and tack it on a board, give the paper a coating of strong glue, size, and then sift a quantity of finely-powdered pumice stone through a sieve of moderate fineness. When the surface has hardened, repeat the process till a tolerably thick coat has been formed upon the paper, which, when dry, will be fit for use.

Lacquering brass work and dipping after the approved manner is a process to prevent oxidation, and so protects brass objects against climatic influences. The effect of dipping is to change the dull reddish hue of castings to a bright tint or brass color; the burning liquid into which the brasswork is dipped hisses and bubbles upon the casting as it is lifted from the bath, removes all impurities and leaves the yellow metal perfectly clean. So powerful is the cleansing agent, that it commences to simmer, and becomes green as the brasswork is removed to the contiguous water-bath, in which it is thoroughly washed and made ready for further treatment in the process of finishing.

To Detect Lead in Tin-Foil.—Frequently it is important to know whether there is lead in "tin" paper or foil. This is the method given for its detection in a leading foreign technical journal: A drop of concentrated acetic acid is let fall upon the suspected leaf, and a drop of a solution of potassium iodide is added. If there is lead present, there is formed in two or three minutes a yellowish spot of lead iodide. Dr. Kopp moistens the leaf to be examined with sulphuric acid. If the tin is pure, the spot remains white, but if lead is present, there is a black spot.

Chinese Ingenuity.—Consul Stevens writes from China as follows: "The department requires us to report any new inventions we may see or that may come before our observation. Thus far I have seen but two. The first is a pump. I remember when I was a small boy, out in Illinois, men came around to sell a new invention, called a chain pump. The same pump has been used here for more than 2,000 years. The second is double-headed tacks. No one can tell me how long they have been in use here. There are many articles in use among the Chinese that could be advantageously introduced in America, of which I have been trying to get some drawings, but they are not yet ready, and will not be in time for this report. They will, however, be forwarded as soon as possible. These implements and machines are very crude, the people being very poor, as a general thing, and utilize everything in their power; they count, almost, the blades of grass; how much it will take to boil a cup of tea, or cook their rice; they never waste for themselves, they only squeeze foreigners.

A New Use for Old Tin Cans and Scrap Tin.—According to the *Berg und Huttenmannische Zeitung*, a better method for utilizing old tin cans than simply to melt off the solder has been devised. E. Roneset first heats the tin, old or new, in an oxidizing flame, which burns up all the pure tin and that combined with iron. When this is stopped, the scraps of iron are seen to be covered with a brown and brittle crust, the upper layer consisting of oxide of tin, the lower of magnetic oxide of iron. It is passed through rollers and then forms a powder that contains both oxides. The iron that remains after sifting out the powder makes good wrought iron or cast iron, but is particularly fitted for precipitating copper. The oxide of tin, although mixed with oxide of iron, can be easily worked into tin, and the metal obtained from it is free from sulphur and arsenic. But will it not contain traces of lead?

Low Water in a Boiler.—If, from any cause the water gets low in the boiler, bank the fires with ashes or with fresh coal as quickly as possible, shut the damper and ash-pit doors and leave the fire doors wide open; do not disturb the running of the engine, but allow it to use all the steam the boiler is making; do not, under any circumstances, attempt to force water in the boiler. After the steam is all used and the boiler cooled sufficiently to be safe, then the water may be admitted and brought up to the regular working hight; the damper opened and the fires allowed to burn, and steam raised as usual; provided no injury has been done the boiler by overheating.

A Big Tree.—The latest big tree story comes from Australia. The tree is described as an almond-leaf gum, 430 ft. in hight, 380 ft. to the first branch, and 60 ft. in circumference at "some distance from the ground." If that tree continues to grow a few hundred years longer, California will have to take a back seat in the contest for the biggest tree.

Tinting Lamp Chimneys.—To stain a glass lamp chimney, paint the glass with a solution of water-glass (sirupy) stained with chrome green, and let it dry thoroughly before using on the lamp.

Good Health.

The Poisonous Mushroom.—Prof. Ponfick, of Breslau, has lately made experiments on the common mushroom, of which the following are the practical results: All common mushrooms are poisonous, but cooking deprives them in a greater or lesser degree of their poisonous qualities. The repeated washing with cold water which they usually undergo to clean them, takes away a portion of the poison, and boiling does the rest; but the water in which they have been boiled is highly poisonous, and should always be carefully got rid of. Experiments made on dogs showed that if a dog ate 1% of its own weight of raw mushrooms, it fell sick, but recovered; if it ate 1½%, the poison had a more violent, but not fatal, effect, and if he ate 2%, it was inevitably fatal. The water in which mushrooms had been boiled was far more poisonous than even the raw mushrooms, while the mushrooms thus boiled could be taken without hurt to the amount of 10% of the weight of the dog's body. Washing with cold water does not remove all the poison, so that mushrooms thus prepared were poisonous when taken in larger quantities. Dried mushrooms are still dangerous for from 12 to 20 days, and also the water in which they have been boiled. They require to be dried for at least a whole month, and are only really safe after four months' drying.—*London News.*

Workers in Lead.—The *Chemical Review* regards it as a lamentable fact that workmen employed in the lead trade neglect or refuse to avail themselves of the precautions devised for the protection of their health. They will not drink the sulphuric lemonade which is given them to counteract the poison; they lay aside the respirators which would prevent the dust and fumes from being inhaled; and, after all, a certain class of newspapers persist in blaming the employers, and in denouncing modern science for not devising a remedy.

Sand and Mud Baths.

In many low plains in the neighborhood of the sea, immense quantities of sand are constantly deposited from the in-rolling waves, particularly at the promontory of Suuium, near Missolonghi, near Corinth, and on some of the islands. These places are visited by persons affected with chronic rheumatism, anchynosis, chronic synovitis of knee-joint, for the purpose of taking a sand bath. The patients, who are generally of the poorer classes, bury themselves in the sand, or cause others to cover them with it, so that only the head, which is covered with a nightcap or straw hat, remains free. It is a ludicrous sight to see 20 or 30 such odd-looking heads sticking out of the sand. In consequence of the weight and the saline character of the sand, the skin of the patients becomes so red, that when they emerge from their sandy bed, which they occupy as long as possible, they look like boiled lobsters. Wooden huts or tents, improvised with oleander and plantain branches, are used as bathing houses, and a piece of bread, some grapes, and a glass of wine generally constitute the meal of a patient. Direct inquiry from the patients has elicited the fact that the effects of this sand treatment are decidedly beneficial.

Another variety of bath is likewise not uncommon, namely, the so-called mud-bath. In the canals and ditches, into which the sea-water is allowed to flow in order to obtain common salt by spontaneous evaporation, a mother-water containing chiefly magnesium bromide remains behind, after the crystallized salt has been removed. At the same time an aluminous mud collects at the bottom. This mother-water, together with the mud, is used by patients affected with chronic splenitis, caused by the frequent malarial fevers prevailing among the workmen in these localities, and with intestinal infarctions. The method consists in smearing the whole body with saline mud, and in exposing themselves afterward to the rays of the sun until the coating has become dry, when it is washed off with the saline mother-water. Sometimes both the sand and mud baths are used locally on a special portion of the body, as, for instance, the legs or feet.—*N. Sanders, M. D.*

Mud baths are used in California. A specially noted location for such treatment is located a few miles east of San Bernardino.

Progress of Homeopathy.—At a recent meeting of the American Institute of Homeopathy, at Indianapolis, Dr. Talbot, of Boston, read a report showing that there are 7,000 homeopathic physicians and 278 institutions in the United States; four national societies report 1,067 members; 26 State societies, 1,783 members; 103 local societies, of which 66 report 2,355 members; 18 clubs, of which seven report 79 members; 23 general hospitals, of which 18 report 1,268 beds; 15 of these hospitals reported having treated last year 6,675 patients. The cost and value of 11 of these is $770,500. Of 30 special hospitals 15 report 859 beds, and 9 of them treated last year 10,609 patients. The cost and values of these hospitals are $1,106,000. Of 29 dispensatories, 27 reported having treated last year 1,469 patients. To these had been furnished 256,589 prescriptions; 12 medical colleges have had 1,267 students, and graduated 412 physicians this year, and 5,680 since they were founded.

Experiments on the Eye.—That sensations of light may be produced by mechanical irritation of the nerve of the eye is now shown to be the case by observations recently made by Schmidt Kimpler, on persons from whom an eye had been removed not long before. A blunt instrument was pressed against that part of the orbit in which the stump of the nerve was situated, and the observations were made in a room almost completely dark. Of six persons, in two pressure on this spot always caused a flash of light on the side of the enucleated eye, and one of them asserted that the sensation exactly resembled that which he had before experienced when the eye-ball was galvanized; the same patient experienced a similar sensation when the stump of the nerve was galvanized. The negative result in other cases is explained by the more complete atrophy of the nerve, or greater retraction of the stump.

Nervous children often suffer from fear when put to bed alone. No tongue can tell the horrors of a lonesome room to such children. A little delicate boy, whose parents were drilling him to sleep alone, used to cry violently every night, and his father would come in and whip him. He mistook his pertinacity for obstinacy, and he thought it his duty to conquer the child's will. One night he said: "Why do you always scream so, when you know you shall be punished?" "Oh, father, father!" said the little fellow, "I don't mind your whipping me, if you would stay with me." The father's eyes were open from that moment. He saw that a human being cannot be governed by dead rules, like a plant or an animal.

Rheumatism is so rare in the earlier years of life as to be hardly ever mentioned by such writers as West and Vogel. Dr. Garden, in the London *Practitioner*, gives the case of an infant of nine months who caught cold from bathing in cold water. Rheumatism followed, affecting the knee and ankle joints. These were wrapped in cotton, and three grains of salicin thrice daily were prescribed. The patient recovered in a fortnight, without showing any signs of heart complication.

Saturday Morning, Oct. 14, 1882.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—An Important Mining Tunnel; Collecting Taxes from Miners; Lead Smelting in Silesia, 241. Passing Events; California Kaolin, 248. The Denver Exposition, No. 9, 248-49. The Darwin Memorial; The Comet, 249 Patents and Inventions; Notices of Recent Patents, 252.

ILLUSTRATIONS.—The Atlantic and Pacific Tunnel; Blast Furnace for Lead Ores, 241. The Argonauta Argo, 243. The Comet, as Seen at Different Times, 249.

MECHANICAL PROGRESS.—Steel Plates for Boilers; Steam Water Wheels; Mortar for Furnaces; Terra Cotta Lumber; Oxygen in Iron and Steel, 243.

SCIENTIFIC PROGRESS.—Curious Electrical Phenomena on Pike's Peak; The Origin and Formation of the Diamond; A New View of the Earth's Evolution; Some Newly Observed Properties of Glucose; No Atmosphere in the Moon; Light Penetration in Water, 243.

NEWS IN BRIEF, on page 244 and other pages.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 244.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana and New Mexico, 244-45.

THE ENGINEER.—Defective Brick Piers; Steam on Street Cars; The Carrying Capacity of Freight Cars; The Largest Wrought-Iron Columns; Over 400 Miles a Day; Pressure in Punching; The Widest Gauge Railway; Exhaust, 247.

USEFUL INFORMATION.—Weales' Description of the Screw; How to Make the Phosphorus Metals; To Make a Good Sand Paper; To Detect Lead in Tin Foil, Chinese Ingenuity; A New Use for Old Tin Cans and Scrap Tin; Low Water in a Boiler; A Big Tree; Tinting Lamp Chimneys, 247.

GOOD HEALTH.—The Poisonous Mushroom; Workers in Lead; Sand and Mud Baths; Progress of Homeopathy; Experiments on the Eye, 247.

MISCELLANEOUS.—Honest Mining; A Mammoth Industry; The Cannon Ball Quartz Crusher; Idaho's Advancement, 242. Manganese for Flux Smelting; Mechanics' Fair Premiums; A Curious Marine Animal; Nostroms Exposed; A Losing Mine; Old California Mining Camps, 246.

Engines and Boilers, W. H. Ohmeu, S. F.

Passing Events.

We notice in our "Mining Summary" several pretty rich strikes in different neighborhoods. It is noticeable also that bullion receipts appear to be somewhat on the increase.

Just now the appearance of the comet is a prolific subject of wonder and of conversation. We have made some engravings showing its appearance, and give them with a description in another column.

This month will probably end the prospecting in a large extent of country. The cold weather will be coming on, and with snow-covered ground little outside work can be done. Many prospectors will probably immigrate towards New Mexico and Arizona, where there are better chances for out-door work in the winter months.

THE injunction papers in the case of Yuba County vs. the Bule Tent and Eureka Lake Hydraulic Mining Companies were received at Nevada City last week. Yesterday a special officer attempted to serve the orders, but when the officer put in an appearance the miners were not working, and the superintendents were nowhere to be found.

THE Oregon Legislature has passed a resolution submitting to the people an amendment to the Constitution conferring the right of suffrage upon women.

The Darwin Memorial.

The scientific work of the late Charles Darwin was of such a nature as to be recognized by the people of all civilized nations. It was not confined within such narrow boundaries as to be only appreciated by a few learned men or a small circle of specialists in one branch of science. His conclusions from his researches were such as to command the attention of thousands who never before gave any heed to scientific truths, as well as that of those who were perusing studies or investigations requiring intelligence of high order.

A short time after Prof. Darwin's death the project was broached of giving the people an opportunity of testifying to their appreciation of his work by contributing to a "Darwin Memorial." The idea originated in England, where a committee of eminent scientific men was appointed to carry it out.

The English executive committee has now asked an American committee to join them in carrying out this work. These gentlemen gladly contribute to the object, and request subscriptions from those who may wish to join in this tribute to the memory of Darwin. The committee is as follows, Asa Gray (chairman), Spencer F. Baird, James D. Dana, Charles W. Elliott, D. C. Gilman, James Hall, Joseph Le Conte, Joseph Leidy, O. C. Marsh, S. Weir Mitchell, Simon Newcomb, Charles Eliot Norton, James A Walker, Theodore D. Woolsey, Alexander Agassiz (treasurer). Subscriptions may be sent to the last named at Cambridge, Mass., who will acknowledge the same and forward them to the treasurer of the English executive committee.

The form which the memorial is to take has not yet been decided; it will probably include an endowment for a scholarship to carry on biological research. Prof. Joseph Le Conte of the University of California, one of the American committee, will lecture on "The Life and Work of Darwin" at the next meeting of the California Academy of Sciences, Monday, October 16th. No fee is charged, but the attention of the public will be called to the project of the "memorial."

Our Lumber Interests.

We have frequently alluded to the results of the census investigations into the extent and condition of Pacific coast forests. The subject is an interesting one, and there is now transmitted from Washington another forecast of results, somewhat different from those we have described before. Concerning California timber it says that the chief trees of the State are redwood, red fir, tide-water spruce, chestnut and red oak on the Coast range; and sugar pine, yellow pine and red fir on the Sierra Nevada. Any estimate of the actual amount of lumber standing in the State, except redwood, is not possible with the existing knowledge of the country. The principal lumber industry is confined to the redwood belt, on the line of the Central Pacific railroad, on both slopes of the Sierra Nevada, to points in Butte, Tehama and Mono counties, and in the San Bernardino mountains. The total product of the State for the census year was 304,795,000 ft. of lumber, 242,400,000 ft. of laths, 138,718,000 shingles, 2,063,000 staves, and 1,393,000 sets of barrel beadings.

In Oregon the most valuable trees are in the order as set down: red fir, tide-water spruce, red cedar, hemlock, Port Orford cedar, white oak, sugar pine, chestnut, oak, larch and scrub pine. The principal lumber industry centers near Portland and Empire city. The product of the coast region for the census year was 151,443,000 ft. of lumber, 17,950,000 lathe and 2,745,000 shingles. The product of the State east of the Cascade range was 25,798,000 ft. of lumber, 295,000 lathe and 2,295,000 shingles.

Washington Territory, according to the *Bulletin*, is covered, west of the Cascade mountains, by the heaviest belt of forest growth in the United States. The most valuable trees in this region are red or yellow fir, covering about seven-tenths of the forest growth, red cedar, hemlock and tide-water spruce. East of the Cascade mountains the most valuable trees are red fir, yellow and white pine, larch, red cedar and hemlock. The principal lumber region is confined to the shores of Puget sound. The product of this region for the census year was 144,387,000 ft. of lumber, 6 550,000 laths, 710,000 shingles and 2,366,000 staves. The product of the coast outside of Puget sound region was 9,599,000 ft. of lumber and 200,000 shingles, and of the territory east of the Cascade range 6,190,000 ft. of lumber and 2,700,000 shingles.

VERY encouraging reports are received from the Live Yankee mine at Spring city, Nev. The owners are taking out considerable rich ore, and they have struck vein matter in the lower tunnel, and expect to strike a vein of ore every foot they advance.

FIVE HUNDRED THOUSAND POUNDS of Idaho freight are lying at Kelton, and teams cannot be found to haul it.

THE cases of cholera at Manila average 30 to 40 daily.

The Denver Exposition—No. 9.

[Editorial Correspondence.]

GUNNISON COUNTY.

During the past two or three years much attention has been given to this county, which is located on the western slope of the continental divide, and which, in extent and apparent resources, forms almost an empire of itself. A large amount of prospecting has been done there within the past three or four years, but the great altitude of most of the mining localities, and the consequent difficulty of getting in machinery and supplies or getting the ore out to smelters or mills has, until within a short time, greatly retarded the proper development of those mines. More recently, however, very ample railroad communication has been opened up by the completion of the Denver and South Park roads, and the matter of transportation has been practically solved. Towns and new cities are now springing up at all the mining centers of the county, even in advance of a full development of the mines, so confident are all in their ultimate value. State Geologist Smith, in his report for 1881, says of the mines: "Judging from what I have seen and the most reliable information attainable, I am fully convinced that, within the next two years, the mines of this county will attain high rank among the best of the State."

Between the western limit of the Leadville mines and the eastern portion of Gunnison county occurs the Sawatch range of mountains, which here forms the continental divide. The wonderful developments of Leadville and the geological similarities, whether fancied or real, between the country there and that portion of Gunnison county just over the divide, not more than 40 miles distant, created the rush which first brought Gunnison into prominence. At first a few prospectors left Leadville, and crossed the divide in search of another Leadville. The reports which they brought back caused quite a stampede for the new El Dorado. The passes in the lofty mountains which they had to cross were, that winter, filled with soft and yielding snow, but so impatient were the earlier ones of the delay thereby caused, that, in one locality, an Immense Deposit of Snow Was Tunneled, So that the land of promise might be reached, and the best localities occupied before the coming summer should open the way for later and more multitudinous arrivals. This emigration, which formed a veritable human tidal wave, crossed in 1880, and founded six different mining camps, which still retain their individualities, and are known as Hillerton, Tin Cup, Pitkin, Virginia, Gothic and Irwin. It is said that nearly 20,000 people summered the succeeding season in the Gunnison region, into which but a few hundred passed the preceding year.

The County and its Resources.

So far as I can learn, however, nothing like the Leadville deposits have been found there; but still a great number of fissure, and, in many instances, true contact veins have been found, far more extensive in numbers, but much less valuable individually than the sulphide and carbonate beds of Leadville. While the outcroppings of these mines are enormous in quantity, and sometimes very rich, the grade of ore, as depth is reached, is comparatively low. Still, to all appearances, the ore is rich enough to pay well for working, while the quartz is apparently inexhaustible. Gunnison promises to become, eventually, nearly, or quite as important, in fissure mining, as Leadville has through its large ore bodies in deposit mining.

Gunnison is often spoken of as the Empire county of Colorado. It is the largest in area, extending from the divide about 150 miles to the western boundary line of the State, and some 70 miles in breadth. The surface of the county—its topography—is as diversified as are its underground resources. The mines of precious metals are mostly found high up on the western slope of the great continental divide. So far as yet explored, this region is somewhat limited—not over 40x20 miles in extent. The western portion of the county is an almost unexplored region. The resources already known are good for a century at least.

Iron, Coal and Lime.

It is not upon the production of the precious metals alone that Gunnison depends for her prosperity. Iron, coal and lime are found in almost unlimited quantity within 30 or 40 miles from Gunnison, the chief city of the county, and at localities which may be readily approached by easy railroad grades. Iron is found in a dozen different localities; within 8 miles are large deposits of brown hematite containing 70% of iron. Inside of 30 miles are immense beds of magnetic ore, while an immense deposit of bog ore, of very superior quality, is equally accessible. This ore assays about 50% in iron and carries from 10 to 12 ounces of silver to the ton. Hematites and magnetic iron ores exist in large quantities in many other localities in the county. Otto Wuth, a well-known chemist of Pittsburg, says of this ore: "There is no better ore to be found anywhere in the United States."

Within the same distance a number of veins of the finest coking coal have been opened where extensive coking works have already been established, and from which coke is being shipped to Denver, Leadville, Pueblo and other places. Near the same locality the best quality of anthracite is also found in extensive and easily worked deposits. The assays of these coal deposits and iron ores afford abundant evidence of their value. Marble, lime and brick clay also occur in inexhaustible beds, and of superior quality. Massive specimens and smaller ones in immense quantities of all those minerals were shown at the exposition. The anthracite deposits can be traced for a length of many miles. At one extremity it occurs as a bituminous coal, at the other as a perfect anthracite—fully as pure by assay as the best Pennsylvania. The intermediate points show all the different grades, while the configuration of the country and the character of the enclosing rocks show unmistakably how by heat and pressure the bituminous has been slowly converted into anthracite coal.

Gunnison City,

The principal town of the county, stands at the gateway of travel between the eastern and western portions of the State. The only practical railroad pass between the two portions of the State has its western terminus at Gunnison City. This pass is already occupied by the Denver and Rio Grande railroad, which is to be continued to Salt Lake, and may eventually form the eastern portion of another transcontinental road between the Mississippi river and the Pacific ocean. From Gunnison various branches are being constructed, north, south and west, as developments bring them into commercial importance. Although scarce three years old, this city is already in active railroad and telegraph communication with all the commercial centers of the country; has a telephone system with some 80 instruments already in use, a system of gas and water supply constructed at a cost of a quarter of a million dollars, a street car company organized which will soon be at work, a police and fire system in full force and usefulness, a population estimated at 5,500, with two daily newspapers, seven churches, a complete municipal organization, two banks, a $100,000 hotel, three $12,000 schoolhouses, etc. If any city of its age can show a better record of push and energy, we should be pleased to learn of it. The growth of Gunnison has been simply wonderful, especially for a mountain town situated within less than 30 miles of the very crest of the Rocky mountains.

The Precious Metals.

The ores of Gunnison county, which carry the precious metals are quite varied in their character. There is evidence all around here, as elsewhere along the divide, of great volcanic and other disturbance. The country rock consists of lime, porphyry, trachyte and granite, more or less altered. The granite appears to have been much fissured. Free gold ores are generally found in that formation, other ores, as of silver, etc., more generally in the other rocks. We have no space to give anything more than a mere sketch of what is being done to develop the resources of this county in the line of the precious metals. This work is evidently assuming proportions of which even the people of Colorado, as a State, have no true conception.

Gothic district is attracting much attention from the somewhat peculiar character of its ores, differing essentially from most of the ores occurring elsewhere in this county. The district made quite a notable exhibit. Some very fine specimens were shown in a case apart from the general county exhibit, consisting of wire silver, ruby silver, etc. The silver mines of this district generally carry a large percentage of gold.

The Ruby district, which takes its name from the large amount of ruby silver found in it, is one of the best known districts in the county. It has quite a number of producing mines. The indications are that it will pass a full half million of the precious metals into trade channels during the present year, with prospect of a steady increase for the future.

The Elk Mountain region is beginning to attract much attention. The interest there is very much divided between the precious metals and valuable beds of coal and iron.

Gold Mining and Mountain Scenery.

There is a mining district lying directly in the mountain pass already alluded to as leading to the gateway at Gunnison city, known sometimes as the Quartz Creek district, but now generally as "Pitkin." The attractions of this district seem to be very much divided between its many facilities, its beautiful scenery and its health giving climate as a place of summer resort. Its location is near the divide. From a mountain summit, three miles north of the town of Pitkin may be counted upwards of 200 towering peaks, planted along the great continental divide from the northern line of Colorado down and into New Mexico. The view here is said to be the finest on the continent. Pitkin will be a great place for summering in the mountains, when its advantages and healthfulness are better understood. The formation here is highly metalliferous. Over 3,000 claims have been located. The bedrock is mostly granite, and is generally covered, except at elevated points, with a deposit of alluvium which almost everywhere carries gold, and is often very rich for placer mining. There are great numbers of greater veins intersecting the granite, many of which are of considerable width and rich in gold. The ore is fine milling, with very fine sulphurets. Separated from the granite by a narrow silverian belt lies a limestone formation, two to four miles wide and 10 miles long, commencing just in the edge of the town. This is intersected by frequent porphyry dykes, between which and the lime are found many contact veins, rich in silver. Much development has already been done all through this region. Some 70 mines of this district were represented

at the exposition, showing several tons of rock. There are seven quartz mills now running or in process in this county, which will operate 100 stamps.

We might make special mention of many other mining localities, did time or space permit. Suffice it to say that the possibilities of Gunnison, so far as can be judged from present indications, are second to no other county in the State; but before closing, one word for her

The Gunnison County Display.

The exhibit of this county was one of the finest and most extensive of any county in the State. At least 40 tons of ore were shown, arranged by districts, very conveniently, for inspection and study. The pavilion in which most of the ores were placed, was the most extensive and elaborate of any in the building. The top of the pavilion was floored over at about the same elevation as the galleries. This floor, with its balustrade, carpet, chairs and table, furnished a very convenient and conspicuous sitting-room, which commanded a finer view of the whole exhibition than could be had from any other locality in the building. It was a favorite resort of visitors, and was frequently occupied by those who happened to enjoy the acquaintance of the commissioners in charge. The floor was reached by a circular stairway, which led up up and through the center of the pavilion.

The Tin Cup district seemed to occupy the place of honor in this exhibit, and the managers made a good use of the advantage, by the erection of a huge pyramid of ores, whose base was surmounted by a series of tin cups, filled with ores, beginning with a cup of mammoth proportions, and terminating with a tiny cup at the summit. The entire pyramid was also ornamented, from top to bottom, with tin cups, ostentatiously displayed. A drinking fountain was also placed within the pavilion, provided with tin cups for the accommodation of thirsty visitors.

In the rear of the pavilion, a large space was fitted up and filled with mammoth specimens of coal, and iron and silver ores, marble and other building stones. One of the largest and richest specimens of iron ore came from the Tomichi district, while there is said to be a solid mass of that ore 100 ft. thick and 3,000 ft. long. A large specimen was shown from another locality, while there were 20,000,000 cubic feet of ore in sight and above ground. Another locality was represented which has millions of tons in sight, averaging 72% of iron. This is mostly a red hematite, which is now largely used for a mineral paint. It is claimed that there is more coal within a circuit of a few miles in this part of the county than can be found in the entire State of Pennsylvania. We have already spoken at considerable length of this coal. It was shown in quantity, and of a quality which could not be mistaken. But we have already extended this letter beyond its proper proportions. W. B. EWER.

The Comet.

At the meeting of the Academy of Sciences, held on Monday evening, Prof. George Davidson, of the U. S. A. Coast and Geodetic Survey, now making observations at a station on Mt. Tamalpais, communicated to the Academy the following memorandum of observations made at that station upon the comet now visible in the eastern heavens at sunrise.

On several days preceding the 19th the weather at this station was very unfavorable, and the morning observations commencing before sunrise could not be made. On the 19th, when I was called before sunrise, the comet was made out among some bright cirrus clouds above the eastern horizon. It was very brilliant, had a well-marked and large nucleus of 10 seconds of arc by about 15 seconds. The envelope was well developed, broad, but not connected with the nucleus, as was the bright comet of June, 1881. Nor was there in the telescope of three inches objective, any marked shadow under the nucleus. The tail was short, but the outer boundaries were bright. The tail was much expanded, being about half a degree long. The eastern side of the tail was the brighter. I thought I detected the western or upper side of the tail divided into three close bright streaks. The form of the tail was that of a wide parabola.

One of the atmospherical phenomena exhibited by the nucleus, was its white light being decomposed into a spectrum—blue, white and red—by its rays passing through the prism of air at that low altitude. This same phenomenon is sometimes remarkably brilliant with Venus near the western horizon. Immediately upon the discovery of the comet, I made observations for its position by observing its altitude and azimuth, and noting the times of observation with a chronometer whose error was well known. (Want of time prevents these observations being reduced.) Near noon of the same day, Mr. Pratt, of the Coast Survey, and myself, got observations of the declination of the comet. It was plainly visible all day to the unassisted eye. [So far as known, these are the earliest instrumental observations on the comet by competent observers.—EDS.] On the 20th, before sunrise, I got other observations for altitude and azimuth, and at noon obtained its meridian transit in the meridian instrument, while Mr. Pratt observed its declination in the Zenith telescope. It was then clearly visible to the naked eye, but its brightness was diminished.

In the morning the nucleus was but slightly diminished in brightness, but the tail had developed in length to about three degrees, although its width was nearly the same at the extremity. At the nucleus the envelope where merging into the tail was not so broad. On the morning of the 21st, the comet presented a most brilliant spectacle. The nucleus was not so large or bright, but the tail was lengthened to five degrees, with a breadth of one-third of a degree at the free extremity. It was contracted near the envelope, and the bright bounding lines of the tail were straight. I made observations for altitude and azimuth, as on previous mornings, and near noon, at meridian transit, its right ascension and declination were determined by Mr. Pratt and myself. The nucleus and part of the tail were then visible to the naked eye.

On the morning of the 22d, the brightness of the nucleus was still more diminished, but the tail lengthened to about six or seven degrees, and the general effect, as a spectacle, was increased, but when the sun rose the comet nearly faded out of sight. There was no sight of a shadow on the nucleus. I after obtained observations for altitude and azimuth, and at a meridian transit determined its right ascension and an approximately close declination. It was not visible to the naked eye.

On the morning of the 23d, I obtained measures of the altitude and azimuth before sunrise. The comet's tail had developed to about eight degrees in length, and was one-third of a degree in width at the extremity. The nucleus was decidedly smaller and fainter. The envelope was contracted, and the narrowness of the tail near the envelope was marked.

After sunrise the comet soon faded out to the keenest eyesight; and at its meridian transit we failed to find it in the meridian instrument and in the larger zenith telescope. On the morning of the 24th there was a remarkable change in the form of the tail. It was slightly increased in length, and about the same width as heretofore at the end; but the eastern white streak of the tail, or cone, was very much curved outward within a degree of the head, while the eastern line of the tail was straight. It seemed to me that two very faint streaks of light projected from the head, nearly at right angles to the axis of the cone of the tail.

Observations were not continued after this date, and the weather was not clear enough for favorable study of the comet's appearance. The remarkable apparent developments of the tail in length may be owing to the two considerations: First, the smoky atmosphere of the first day or two; second, the prospective view of the comet when more directly in line between the sun and the earth at the earlier rates. I could not leave my duties at this station to observe for position and physical peculiarities at my San Francisco observatory; but I add the position of the comet as determined on several dates at this station.

U. S. Coast and Geodetic Survey station, Table mountain, latitude 37 degrees, 55 minutes, 20 seconds, north. Longitude west of Washington, 3 hours, .02 minutes, 10.96 seconds. Elevation above the ocean, 2,604 ft.

Table Mt., Mean Time. Meridian Passage.	A. R. Comet. Hrs. Min. Sec.	Decl. Comet. Deg. Min. Sec
Sept 20, A.M. 11h, 15m, 18.7s	11 13 37.7	Sth 0 39 58
" 21 " 11h, 06m, 2.36s	11 08 37 2	Sth 1 24 11
" 22 " 10h, 58m, 10.8s	11 04 21.2	Sth 2 07

The observations of previous and subsequent dates out of the meridian have not been reduced.

The observations of previous and subsequent dates out of the meridian have not been reduced. It should be mentioned as a matter of interest to observers that the meridian instrument with which the right ascension was determined is a Clark objective of only 2¾ inches; and that the objective of the Zenith telescope is 2¾ inches in diameter. Moreover, that on the 19th and 20th, when the comet was readily found with the naked eye, we failed to see Venus at the same time, although at a much greater angle from the sun.

Since the above paper was written, some further observations have been made. Prof. Davidson has kindly made for us a series of sketches of the comet as observed on different days. Four of these sketches we have hastily engraged, to illustrate its appearance at different periods.

Fig. 1 of the engravings shows the comet as first seen on September 19th at 5 A. M. It was then three-fourths of a degree long and half a degree wide; nucleus, 10 seconds by 17 seconds.

Fig. 2 shows it on September 21st at 4:30 A. M. It was then three degrees long and half a degree wide.

Fig. 3 shows it on September 24th at 4:30 A. M., when it was eight degrees long. This shows the curved eastern border, and also the rays at right angles at the point.

Fig. 4 represents it at 4:15 A. M. on October 7th. The length then was 12° to 15°; width, ½° to 1°; exceedingly brilliant. The nucleus sometimes appears separated into two parts (atmosphere not steady), and certainly is not symmetrical with focus of envelope. There is now shown a secondary comet—very faint, but certain, and with its head near a small star, one and a half or two degrees from the large nucleus. This is shown in the engraving. These ents, of course, do not show the proportionate length of tail.

It is not known whether this is a new comet or not. Opinions differ greatly, so far, among astronomers. It is the most beautiful which has appeared for many years, and thousands of people rise early to see its magnificence.

FIG. 1—COMET ON SEPT. 19TH. FIG. 2—AS SEEN SEPT. 20TH.

FIG. 3—RAYS AT RIGHT ANGLES NEAR NUCLEUS, SEPT. 24TH.

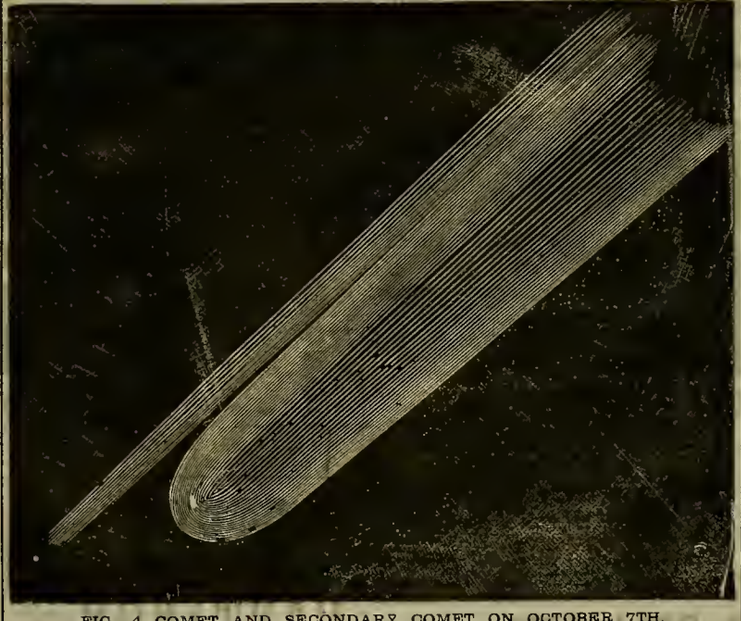

FIG. 4 COMET AND SECONDARY COMET ON OCTOBER 7TH.

THE TAXES TAKEN OFF THE LEAD PILE.—On the 30th day of September, 1882, the Board of Commissioners of Eureka county, sitting as a Board of Equalization, present, A. W. Campbell, Nathan Smith and C. M. Mikel—full Board—the application of the Richmond mining company of Nevada to have its taxes equalized and reduced in accordance with its complaint was heard and considered. It was ordered that the taxes of said company be reduced in the sum of $300,000, and that the said sum of $300,000 be remitted from its assessment. The Richmond "lead pile" had been assessed at the sum named, and the cutting off of it is what is meant. In other words, the "lead pile" is to pay no tax.—*Eureka Sentinel.*

DURING the last three months, of this year, the mines of Leadville have produced lead, silver and gold worth $4,619,547.40—the largest yield in the history of the camp,

THE Copper King mine, Sante Fe district, Nevada, is said to have 45,000 tons of ore in sight.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LAROEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Olant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

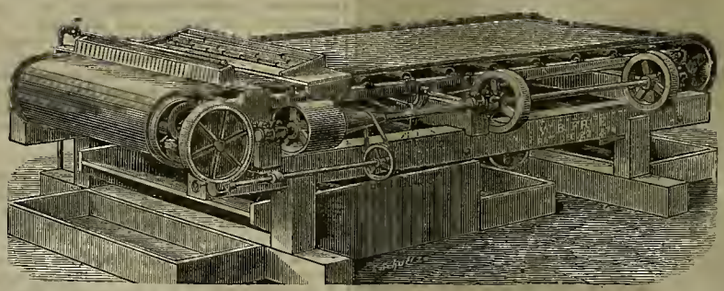
$1,000 CHALLENCE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

READY FOR DELIVERY.

LATHES, DRILLING MACHINES, PLANING MACHINES

and Other Machine Tools,

STRONG, DURABLE AND SUPERIOR TO IMPORTED MACHINES.

Wheel Cutting to Order.

SAN FRANCISCO TOOL CO., - - 21 Stevenson St., S. F.

Colorado Iron Works,

MANUFACTURERS OF

ENGINES, BOILERS, RAILWAY CAST AND WROUGHT WORK, BRIDGE WORK, BOLTS AND BOLT ENDS, BUILDING WORK, ETC.

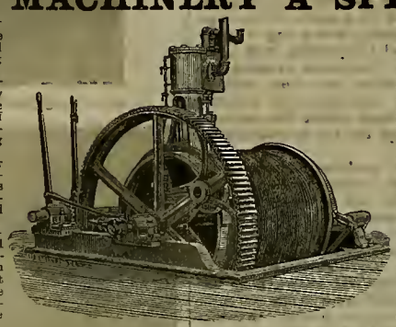
MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the



following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupelation Furnaces, Market Kettles, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES,

SAVE YOUR GOLD!

— BY USING —

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save more gold than any other method, and double the amount of the same surface of ordinary copper plates. The only plates that have proved durable and satisfactory.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

San Francisco Gold, Silver and Nickel Plating Works,

653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

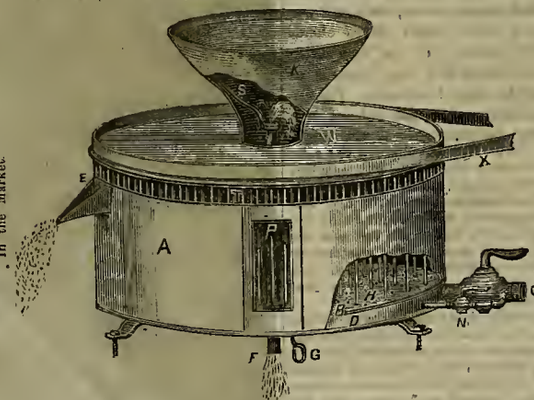
Send for Circular —EDWARD G. DENNISTON, PROPRIETOR.

Awarded the First Premium at every Fair of the Mechanics' Institute for the last 12 Years.

THE RAPID ORE CONCENTRATOR.

Patented March 28, 1882, by G. A. METCALF, of Malden, Mass.

CHEAPEST AND BEST **CONCENTRATOR** In the Market.



HAS RECEIVED THE **COMMENDATION** Of the Best Judges.

For further Particulars address the Inventor.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequaled strength, toughness and durability.

An invaluable substitute for forgings or cast-iron requiring three-fold strength.

Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.

15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.

CRANK SHAFTS, SHOES, DIES and GEARING specialties.

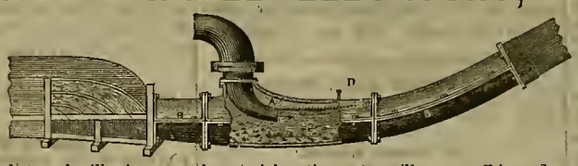
HYDRAULIC GRAVEL ELEVATORS,



For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

ESTABLISHED 1868.

GOLD SAVED

BY USING MY

SILVER PLATED AMALGAMATING PLATES.

These Plates are used in Quartz, Gravel and Placer Mining with gratifying success. I am constantly filling orders for them, and when once used they prove themselves so superior to any other process yet discovered for saving Gold that my customers would not do without them. I have the best facilities on this coast for filling orders for these plates, and will guarantee my work. Old Mining Plates Bought, Taken in Exchange for New, or Re-plated.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR THE WEEK ENDING OCTOBER 3, 1882.

265,306.—WATER, GAS, SEWER OR DRAIN PIPE—John P. Culver, Tucson, A. T.
265,490.—ROCK CRUSHER—A. G. & J. M. Dyer, S. F.
265,328.—SIDE-HILL PLOW—P. I. Knapp, Half Moon Bay.
265,331.—BRIDGE—Wm. Litell, Noise City, I. T.
265,321.—ARCHED GIRDER—P. H. Jackson, S. F.
265,322.—VENTILATOR—P. H. Jackson, S. F.
265,445.—WRENCH—P. Potermund, Eureka, Cal.
265,461.—CLOTHES PIN—Thos. A. Sweet, Cambria, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

VENTILATOR.—Peter H. Jackson, San Francisco, Cal. No. 265,322. Dated Oct. 3, 1882. This invention relates to an improved ventilator for soil-pipes, chimneys, flumes, etc., or for any place in which impure air or foul gases are liable to generate, or within which there is imperfect ventilation. This invention consists in the provision of means for inducing an independent draft or current in such relations with the body of impure or foul air or gas, that a part shall surround, and another part be inclosed by said body of impure air. The general principle of operation is well known, and needs but a short reference. In pipes wherein foul air or gas has accumulated, or in which there is imperfect draft, the air, being heavy, will not pass off. In all ventilators of this class, an independent draft is effected, in such a relation with the body of foul or heavy air as to cause the latter, by induction, to rise and clear the pipe. In some devices the body of foul air is surrounded by, and in others it surrounds, the actuating draft or current, in either case but imperfectly inducing the latter, as it acts upon one edge only; but in this construction the invention combines both features—surrounding and being inclosed by the air to be induced—wherehy the whole body of the latter is acted upon and drawn out.

WATER, GAS, SEWER OR DRAIN PIPE.—John P. Culver, Tucson, Arizona. No. 265,306. October 3, 1882. This invention relates to certain improvements in the formation of continuous pipe for the purpose of conveying water, gas, or other fluids or liquids, and it consists of sheets of metal sufficiently long to form the sections, and of a width to form two or more thicknesses when rolled into a pipe of suitable size. The sections are formed hy rolling the sheets in a hath of molten solder, which, flowing hetween the thickness of the metal, unites it into a solid multiple-walled tuhe during the operation of rolling, and without further treatment of any kind, having the outer surface finished with a coating of tin. The pipe section thus prepared may he joined in any desired manner to form the lengths required when laid.

MACHINE FOR MAKING WIRE ROPE.—A. S. Hallidie. No. 264,529. Patented Sept. 19, 1882. This machine is especially designed for the manufacture of wire ropes or cables, already patented hy Mr. Hallidie, in which the wires forming the strands are drawn to a section other than round, so as to present a flattened exterior surface for wear, and thus prolong the life of the cable. The present invention consists in the combination with a rope-making machine, of a series of dies or formers through which the wires are led, and hy which they are drawn into the desired shape before they are laid up into strands and ropes. By means of suitable mechanisms these wires are kept in the proper position, so that unless they pass through the strand forming die they will he laid with their flattened sides outward.

APPARATUS FOR CAPPING, UNCAPPING AND LOADING CARTRIDGE SHELLS.—L. Sontagg, S. F. No. 264,204. Dated Sept. 12, 1882. This invention relates to an apparatus for performing the work of crimping, capping, loading and decapping cartridge-shells. It consists of a holder for the cap and shell, and a lever hy which the cap is seated, a block for setting the hullet after the powder has been introduced into the shell, a movable post with a pin, which may he hronght beneath the lever after the discharged shell has been placed upon it, so that, hy pressing down upon the lever, the cap will be forced off, and a device for crimping the open ends of the shells.

DITCHING PLOWS—Abraham Kirkpatrick, Bridgeport, Mono Co., Cal. No. 265,102. Sept. 26, 1882. This invention relates to the class of plows, and more especially to those adapted to make a trench, and commonly known as ditching plows. The object of this invention is to provide a plow for ditching and irrigating purposes, which will he simple and economical in construction, effective in operation, and easy of transportation. This invention consists of certain details of construction for carrying out this object.

ARCHED GIRDER.—Peter H. Jackson, San Francisco, Cal. No. 265,321. October 3, 1882. This invention relates to certain improvements in the construction of sectional cast-iron arched grinders, by which the tensile strain upon the tie-rods and the compressive force upon the cast-iron arch are better distributed and equalized. It consists in such a construction that the abutting parts of the sectional arch always meet on a line with the intrados of the arch, whatever may be the deflection under loads, and also in connecting the joints or meeting ends of the section with the tie-rods, by intervening vertical connecting struts, which serve to transmit the strain from arch to tie-rods, so that any deflection of the arch is resisted by the tie-rods, and all vertical strains are resisted by both the arch and the rods.

SIDEHILL PLOW.—Robert I. Knapp, Half-moon Bay, Cal. No. 265,328. October 3, 1882. This invention relates to certain improvements in sidehill or reversable plows, and it is more especially applicable to a plow for which letters patent were issued to the same inventor on the 7th of September, 1875. This present invention relates to an improved means of securing and swiveling the share to the frame, and a means of swiveling and locking the beam, so as to throw the plow to or from the land. It also relates to an improvement in the form of the share in its right or left position.

STREET CAR.—Samuel Howe, Oakland. No. 264,948. Sept. 26, 1882. This invention relates to certain improvements in cars, and it is more especially applicable to street cars. It consists in sundry details of construction, as hereinafter fully set forth, and specifically pointed out in the claims.

OVERALLS.—Moses Greenhaum, S. F. No. 264,944. Dated Sept. 26, 1882. This invention relates to certain improvements in pants, or overalls, for boys' and men's wear, and it consists in a novel method of cutting, whereby the crotch seam is strengthened.

Nothing Succeeds Like Success.

When an article of real merit is placed on the market, it is astonishing with what rapidity it is introduced and taken hold of, while its very name becomes a household word. The marvelous success of the New England Baking Powder proves this. When first brought to the notice of the public, the market was overcrowded with different brands, and the proprietors of the New England were discouraged by dealers and attacked on every side by manufacturers. But, confident in the superiority of their goods, and satisfied there was plenty of room at the top, where they belong, and where they were determined to be, they still pressed on, and gradually, as one family after another throughout the country gave this baking powder an intelligent trial, its merit became more and more known and appreciated, until now it is more generally used on this coast than any other brand. Not only are the sales in the Pacific States very large and constantly increasing, but orders are being received from Salt Lake, Denver and Texas, and influential parties in Chicago and other Eastern centers have applied for the agency, and also for terms to manufacture on a royalty. The proprietors, however, do not propose to let their process out of their hands or out of the State. The ingredients, as well known, are only the very highest grades of refined cream of tartar and bicarbonate soda, but the proportions and method of combining the same, so as to insure strength, uniformity and keeping properties, are peculiar to the New England alone, and in these it has no rival. * * *

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,
No. 252 Market St., S. F.

Old Papers Wanted.

Twenty cents each will be paid for a limited number of copies of any of the following Nos. of the MINING AND SCIENTIFIC PRESS, if received soon at this office: No. 1. of Vol. 13, 1866; No. 5. Vol. 18, 1869; Nos. 1 and 26, of Vol. 20, 1870; No. 1, of Vol. 22, 1871. Also, 10 cents per copy for Nos. 2, 3, 4, 7, 10, 11, 12, 13 and 15, of Vol. 30, 1875. If any one who has files of back volumes of the PRESS, which they may like to dispose of at a moderate rate, will send us a memorandum of the same and the price, we may be able, sooner or later, to assist in their disposal.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Mining and Other Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

DIVIDEND NOTICE.

OFFICE OF THE

"THE $1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in Use in the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Uintah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King" Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sofa" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

WATER JACKET SMELTING FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN SIXTY of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to examine mines and to superintend construction and running of furnaces. Estimates given upon application.

Send for circular.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

Contains no Nitro-Glycerine or Chlorate of Potash, and is the only High Explosive Manufactured in America that does not contain these Dangerous Ingredients.

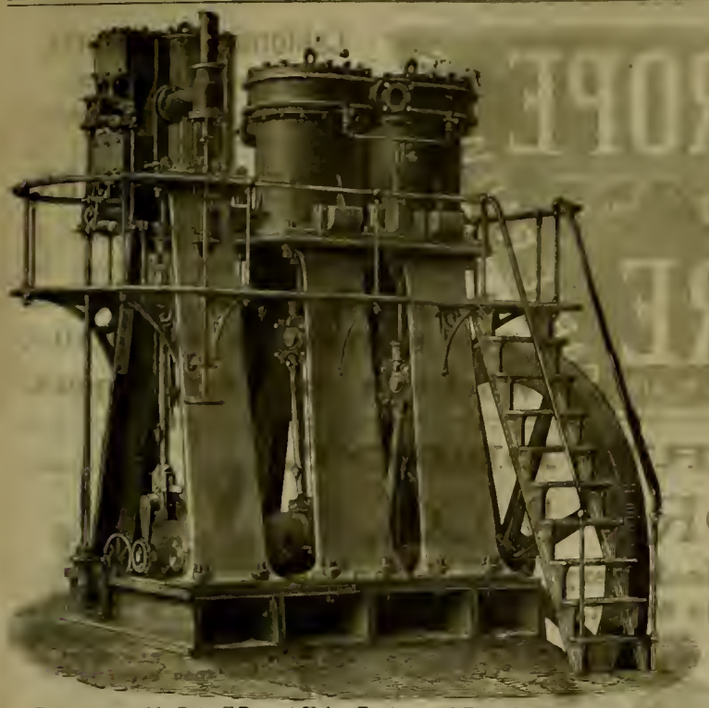
ASTHMA. The greatest proof of the genuine merit of an article can be found in the amount of patronage it receives, and the thousands of testimonials respecting Dr. Hair's Asthma Cure, proves most conclusively that it is all that it is represented to be. Dr. HAIR'S Treatise on Asthma and Hay Fever contains a list of cures from every State and Territory in the United States, also from every Dominion of Canada, England and Scotland. Treatise sent free, address Dr. B. W. HAIR & SON, Cincinnati, Ohio.



With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

NATIONAL COMPRESSORS and ROCK DRILLS.

EDWARD A. RIX, Agent,

Successor to **REYNOLDS & RIX,**

No. 49 Fremont Street, San Francisco, Cal.

MANUFACTURERS OF AND DEALERS IN

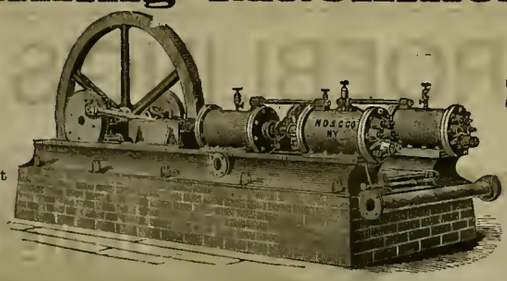
Mining Machinery.

We manufacture the

BEST

Air Compressors

Ever driven by belt from Water Power.



Hoisting Rigs.

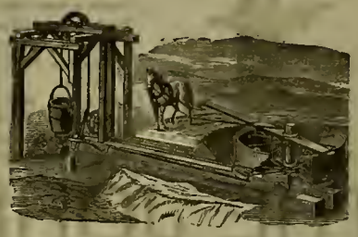
DONKEY ENGINES

For Pile Driving.

MINING CARS,

Ore and Water

BUCKETS.



MINERS' HORSE-WHIM.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

MILL AND MINING MACHINERY.

Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by

F. A. HUNTINGTON, 220 Fremont St., S. F., Cal. | FRASER & CHALMERS, 145 Fulton St., Chicago, Ill.

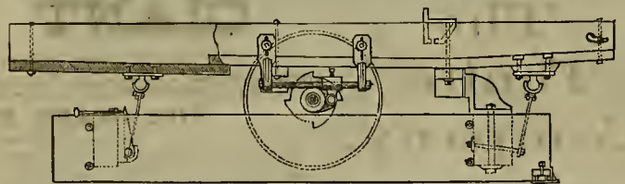
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,

220 Fremont Street, San Francisco, Cal.

F. A. HUNTINGTON,

No. 220 Fremont Street, - - San Francisco, Cal.

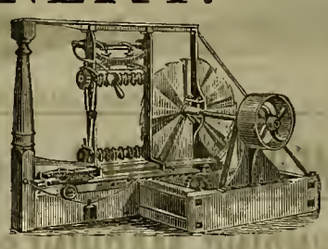


PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in very short time. One machine will concentrate the tailings from a five-stamp battery.

☞ Send for Circulars. ☜



SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

F. A. HUNTINGTON,

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to wate. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

NOTICE.

The old firm of MOREY & SPERRY, Manufacturers and Dealers in Mining Machinery, having been dissolved, a partnership has been formed between Eugene Sperry, Dudley S. Steele and Nathan W. Condict, Jr., under the firm name of SPERRY & CO., to continue the manufacture of and dealing in all kinds of Mining Machinery and Supplies for Mills and Mines.

MR. JAMES A. SPERRY, formerly of the firm of Morey & Sperry, whose experience extends over a period of 33 years, commencing in California in 1849, and embracing the western and southern sections of the United States, as well as Mexico and South America, will personally superintend the construction of the Machinery, and when desired, the erecting and starting of the same upon the ground.

The Machine Works and Foundry of MESSRS. STEELE & CONDICT in Jersey City will be especially at our service in filling orders, and we feel confident that our facilities will enable us to fill orders understandingly, promptly and at reasonable prices. Information and estimates will be cheerfully given.

SPERRY & CO.,
Office, 95 Liberty Street, New York City. Works, Jersey City, N. J.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, OCTOBER 21, 1882. VOLUME XLV Number 17

Academy of Sciences.

The regular meeting of the Academy was held on Monday evening last, Prof. Davidson in the chair.

The Academy's museum was increased by numerous donations, and among the more interesting objects were a mounted marmot from the Sierras in California, presented by a donor who had never heard of its existence in this State; a wooden carving of the "Greek Slave," the work of Queen Charlotte Indians, British Columbia; a peculiarly constructed mortar and pestle for grinding cereals, discovered by a blast in the New Almaden quicksilver mine, and uncovered at a depth of some 150 ft. below the surface.

E. F. Lorquin exhibited and dilated upon the hanging nest of a California oriole, which he considered remarkable in that it was made up of various colored bunches of worsted, also comparing it to the woolen nests of the titmouse, and that of the great pensile and ponchlike nest of the Mexican oriole, which is made of grasses and flexible twigs.

Some sixty specimens of minerals were also presented, among them being 20 specimens of a substance very like soapstone croppings, and found by D. Grosper in a ledge from 40 to 60 ft. wide near San Francisco; also a vial of black auriferous sand, found on the beach in Los Angeles county, and sulphurets of copper found on the Oak ranch, Bolinas, Marin county.

Dr. Behr exhibited one of the mud and clamlike structures which the "mason bee" builds, calling especial attention to the remarkable instinct of the mother insect in providing the structure with sufficient pollen and honey to last the larvæ until a state of insect perfection has been reached.

Professor Joseph Le Conte of the University, and one of the gentlemen selected by the English Executive Committee of the Darwin Memorial to join it in carrying out this work, appeared before the meeting and treated of the genius and life work of the dead scientist. He explained at length the work done by Darwin and its grand results.

With respect to the comet and the wild speculations concerning it, Prof. Davidson announced that there was nothing authentic as to the nature and character of the heavenly visitor. It would appear, however, from the last number of *Nature*, that on Sunday, the 17th of September, A. A. Common, of England, while observing the sun with a special telescope, found a fine comet near the sun's nucleus. This was its first discovery. He explained quite fully the theories of comets, their paths, formation, etc., and read a paper on them. The whole paper was a very interesting one.

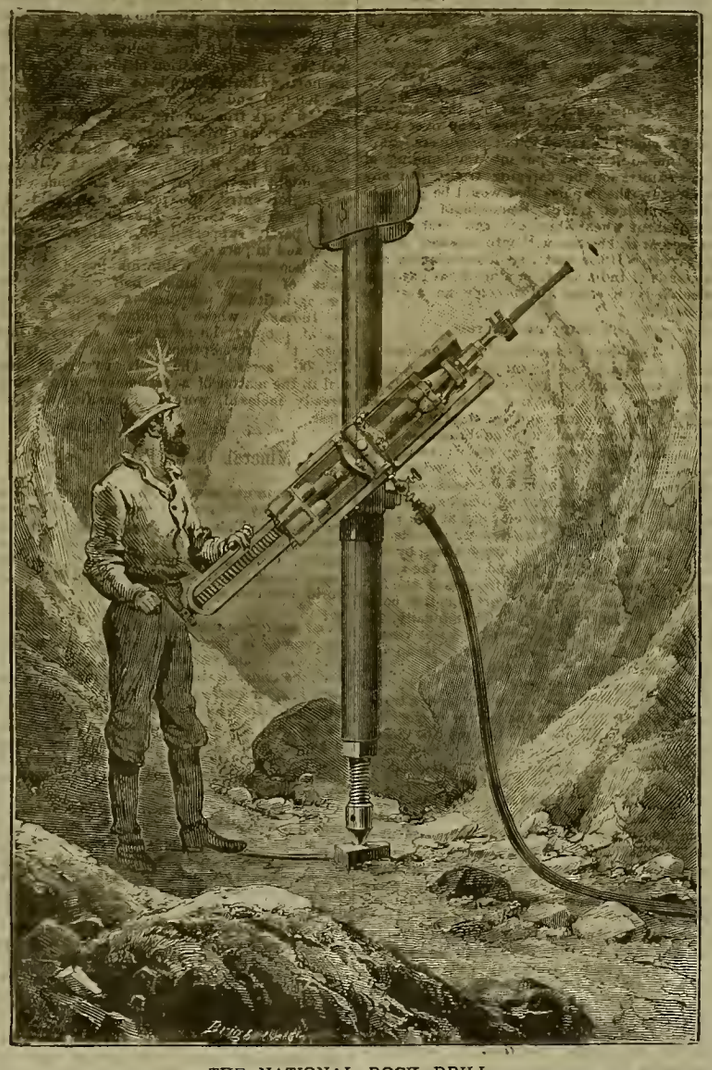
Pyramid Lake District.

This district is 30 miles north of Reno, in Washoe county, Nevada, from which point it is easily accessible by a good wagon road at all seasons of the year. The principal development of the district has been in the Jones & Kinkead mine, which has been prospected to a depth of 400 ft. by means of an incline shaft. Crosscuts have been made at the 100, 200, 300, 330, 370 and 400 levels, all showing a well-defined ledge 40 ft. in thickness, and assaying from $5 to $400. The upper levels show free-milling ore, while the lower, or 400 level, is rich in both silver and copper, shipments of which have been made to the Denver reduction works, giving net returns of $100 per ton. Work in the lower level was stopped by water, and a tunnel is now being run which will tap the vein at 550 ft., or 150 ft. below the present workings. The tunnel, when completed, will be 1,250 ft. long, of which 500 ft. remains to be run.

This mine gives evidence of becoming a valuable property. There are many other claims in the district of less note, but showing good prospects. The Crown Prince adjoins the Jones & Kinkead on the southeast. It has been prospected by a tunnel, which taps the ledge 150 ft. below the croppings, showing the same character of ore as the Jones & Kinkead. Many other locations show equally good surface indications, only wanting energy and a little capital to show their worth and value.

The National Rock Drill.

The National rock drill differs from other rock drills in several particulars. Among the first excellencies claimed for it is the positive and simple valve motion. It has a chuck that takes the steel in the octagon shape, thus saving the turning of shanks; and it has an adjustable take-up for the lost motion on the feed screw. The wear and tear is claimed to be less than in other drills, it requiring but one-third the number of duplicates. The principal office of the company making the drill is at 78 Center street, New York, and Edward A. Rix, 49 Fremont street, in this city, is the agent for this coast.



THE NATIONAL ROCK DRILL.

These drills are in use all over the coast. Among the principal mines to be mentioned are the Idaho mine, Sierra Buttes mine, Amador Pacific, Yuba Compromise, Mahoney, Empire, etc. The work on the tunnels on the Oregon & California R. R. is being pushed ahead by using 15 of these drills, which have given great satisfaction. We hear that the progress on one end of the Wolf Creek tunnel, using four of these drills on columns, was 220 ft. of finished tunnel during last month. In addition to the mines mentioned, where the drills can be seen at work, they may be examined at the agent's in this city, at the address given above. Mr. Rix is also a dealer in hoisting rigs, donkey engines, steam pumps, air compressors, horse whims, water wheels, air receivers, ore and water buckets, etc. A number of these things he manufactures. The rock drills are so well known that no detailed description of them is necessary.

LOST BOTH EYES.—Wm. Turner, who had an eye torn out by the explosion of an unfired cartridge which he struck with his pick while working in the Idaho mine, several weeks ago, has lost the sight of both eyes. For a time it was hoped that the sight of the remaining eye could be saved, but it was so badly injured that hope had soon to be given up. This is a terrible affliction, which arouses the warmest sympathy of the many friends of the injured man.—*Grass Valley Union.*

THE tailings, mill and other property of Whitney, Veasey & Co., at Cornicopia, have been turned over to the creditors of the company, who will continue to run the mill with a view of recovering their losses.

STRIKE.—A dispatch from Austin, Nevada, dated the 17th, says: The Nevada mining company, Manuel San Pedro, superintendent, has made a big strike. Ore now being taken from their mine in Gold Park, Nye county, assays very high.

A New Rock Crusher.

Aaron G. Dyer and James M. Dyer, of this city, have patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, an apparatus for crushing ore, which possesses some peculiar features. They make an outer cylindrically-shaped vessel of sufficient thickness to resist any strain which may be brought upon it. The inside of this cylinder is straight, or nearly so, to a point near the bottom, where it curves inward, and thus contracts the opening at the bottom, and at the same time makes the sides thicken at that point. The bottom of the cylinder thus thickened has a groove formed in it, and the base-plate has a corresponding circular groove, so that a series of balls, fitting into these grooves, support the cylindor so that it may turn freely upon them.

There is a journal at the top of the line with the axis of the cylinder, and it has an arm projecting a little to oneside. Through this arm, and into the center of the base-plate, an axis extends at an angle, and is fixed firmly in place. Upon this axis is a conically-shaped block of metal fitted to turn loosely. The bottom of this block is curved to a corresponding curve, while the opposite side will, on account of the angle, stand a little higher and away from the side of the cylinder, so as to leave a space for the escape of the crushed rock. Collars are secured to the axis above and below the block to hold it in place or to allow its adjustment.

Upon the exterior of the cylinder is formed a gear, and a pinion serves to drive it. A hopper serves to introduce the ore or rock to the upper end of the cylinder, and a screen allows the escape of the pulverized rock when it has become fine enough. A roller, or rollers, are fixed to the frame outside the cylinder, and press against it at the point where the inner cone comes most closely in contact with it, so as to prevent the strain of the passing rock from forcing it out of place.

The operation is as follows: The outer cylinder, being set in motion, rotates without moving the inner cone, which is, however, free to turn upon its shaft or axis. When rock is fed into the space between the two it will seek the widest portion, where it becomes wedged, and will thus carry the inner cone around with the outer cylinder. While thus acting to bind the two together, the rock is carried around with them, and as the space becomes narrower the rock will be crushed and fall lower, the operation being repeated until the rock finally falls through the discharge space. From this point it passes beneath the balls, and is further crushed by the weight of the cylinder until it will pass through the screens. It will be seen that the two parts may be reversed in position and work the same—that is, the interior solid portion may be cylindrical in shape and the exterior hollow portion may be cone-shaped or tapering, so that the side will approach in the same manner as before described, and the crushing be done in the same manner.

ANOTHER ATTEMPT TO ENJOIN THE HYDRAULIC MINERS.—The true inwardness of Sheriff McCoy's visit to this city last week is now before the people, or will be by the time this article is read. McCoy actually did bring with him injunctions issued out of the Superior Court of Yuba county versus the Eureka Lake and Blue Tent Hydraulic Mining Companies. These papers he turned over to Sheriff Tompkins during his stay here, and on Friday Tompkins had one John Holbrooke of this town appointed as a special deputy to serve them. These various proceedings were known to a few of the miners' friends about as soon as they transpired, but they assumed a lamb-like innocence and pretended to know nothing. Sunday evening the man Holbrooke slipped quietly out of town on his "still hunt." He was surprised to find upon his arrival at the mines that his coming had been anticipated, and the bad, bold hydraulicers he was in search of had flown.—*Transcript.*

THE *Tribune* says that during the month of September the deposits of bullion at the Carson Mint were greater than any single month since operations were resumed, on November 1, 1882.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Wallapai District, Arizona.

EDITORS PRESS:—Being a constant reader of your valnable journal, and seldom seeing nnything in it about this section of Arizona, I thought I would drop yon a few lines, thinking that some of your readers might want to know where we lived, or know what we are doing, or what we have got in the shape of mines, our facilities, etc., and to have a little chat with them, and to let them know we are still here, staying with the pot, happy and contented, but, of course, living in anticipations; some of us, like McCawber, "waiting for something to turn up." But this district has had its ups and downs. In fact, it has mostly ups.

Many a poor prospector has made from $15,000 to $75,000 in this district from the surface, which nothing has ever been said about, and to-day hut very few of them have a dollar to show for it. Some sold out and left the country; others, after spending their money in having a good time in San Francisco or back East, came back broke; they tackled their old ground again, but failed to find it as they once had it. They found they had to go down, and as they had neither money nor credit it was hard for them to go down in hard ground. So lots of them got disgusted, cursed the camp and left it, never to come back. But they are coming back all the same; after traveling, the Lord knows where, here they come broke—no money, in fact, no clothes. Now, who'e to blame for that? Is it the country? Well, I should remark, of course it is.

But there's another lot of fellows who do the country more injury than they, and they are the ones who call themselves experts and capitalists, who can tell you what is in a hill just by looking at it a mile away, and who come into a camp at night and leave in the morning, and, in fact, go off forgetting there was a landlord in camp, and saying they had very urgent business in 'Frisco or New York or South America; any where but here. Now, why is it thus? We have an excellent climate, plenty to eat, and charges are moderate. A man can get good hoard for $10 per week; why can't they stay a week, and take a square look at a hill, anyhow? No, sir, they won't do it; hut they will go off and tell the parties who sent them here that there is nothing in the country. Bnt they lie when they think it. I have prospected and mined for 20 years, and I stake my reputation as a miner that there is more mineral lying idle in Wallapai mining district and on the surface than any other district on the Pacific coast or any other discovered district.

'Tis true, our facilities for working ores are limited. There is hut one five-stamp mill to work custom ore in the district, and we cannot handle any ores which will work under $200 per ton. I venture to say, however, that same mill has turned out more money for the time it has run and the amount of stamps than any mill on the coast, and for some reason there is not one word said about it. We have a paper published here called the *Alta Arizona*, and there is hardly ever a word in it about our mines or mining interests. But we are still here picking away, and some day not long hence we will show to the world that we have the mineral here. With the advent of the A. and P. R. R. through our county it will form a new impetus to our mining industry.

I contend we have the mines here, and they go down as far as any one has ever went, hnt we are poor men, and, as the ore is low-grade, it takes money to get it ont. We can't give all our labor to a mill company. I know of one mine here out of 50 or 60 that has over 5 ft. of $40 ore, and in the veins there are large kidneys of rich ore which will mill 120 ozs. in silver and 30% lead—hut mayhe they are no account. They are here, all the same, and will be worked; and I hope they will he worked judiciously. There have been a few failures in the county, and I am afraid that there will he more; and if there are, I say it openly, that it will be by injudicious management. In my next I will give you a brief sketch of our mines and their workings. W. H.

Mineral park, Wallapai district, Mohave county, Arizona.

IRON ORE.—We have received from "D. S. P," of St. Helena, Napa county, several fine specimens of iron ore from that locality. The mine is for sale, and anyone interested may examine the specimens at our editorial rooms. There is considerable attention being paid to iron deposits in this State just now. The ore we refer to appears to be of good quality.

TRUSS BRIDGE.—William Litell, Boise City, Idaho. No. 265,331. October 3, 1882. This invention relates to that class of bridges commonly known as "truss bridges," and more particularly to the sub-class "lattice truss bridges," and it consists in certain combinations and arrangement of devices for improving these bridges.

THE Hamburg-American steamer *Herder* is ashore on the Newfoundland coast, and will prove a total loss, but no one was drowned.

Pacific Coast Interests.

There was quite a norable meeting held in this city on Tuesday of last week. It was a conference between the representatives of the State at Washington and the leading business men of San Francisco, and the subjects for discussion were several public enterprises calculated to advance Pacific coast interests, to-wit: "The Incorporation of the Nicaragua Maritime Canal Company," "The American Commercial Marine" and "The Bill regarding the Tenure of Public Lands." There were present United States Senators Farley and Miller and Representatives Rosecrans and Page, and nearly all the prominent merchants of the city. The main facts were brought forward by the local side of the meeting, the Senators and Congressmen stating that they agreed in the main with the views advanced, and would labor to get Congress to enact as the sense of the meeting required.

Concerning the Isthmus canal, the following, introduced by Captain W. L. Merry, was unanimously adopted:

WHEREAS, A bill authorizing the incorporation of the Maritime Canal Company of Nicaragua, has been favorably reported by the Committee on Foreign Affairs during the last session of Congress; and,

WHEREAS, The Legislatures of Oregon and California, by concurrent resolutions, the representative commercial bodies on the Pacific coast, and thousands of our producers and merchants, have petitioned Congress, urging the passage of this bill as a matter of vital importance to the Pacific coast, beneficent in its results to our whole country and the commercial world; therefore, be it

Resolved, That the Board of Trade of San Francisco extend to our honored Senators and Representatives in Congress its thanks for their friendly assistance to the bill authorizing the incorporation of the Nicaragua Canal Company, and respectfully urge upon them the necessity for their active co-operation in securing its final passage and the Executive sanction during the next session of Congress.

C. J. Dempster stated that hy the canal, in the moving of one single wheat crop over $12,000,000 would be saved to our producers. Suppose this addition was put into the building of iron steamers for the carrying trade, can any one picture the impulse that would he given to every branch of trade? Some doubt whether our present wheat shipment can continue at its present magnitude without increased means for export. If the vast Red River country and the lands of India are to produce what has been calculated, the canal will become an absolute necessity.

The Shipping Interest.

C. T. Hopkins, Chairman of a committee to draft a memorial on the subject, "The American Commercial Marine," read the result of their labors. The substance of the document is: That the immense and constantly growing foreign carrying trade of San Francisco, now the sixth among the 93 seaports of the Union, is so completely in the hands of foreign ship owners that only 12 out of 550 vessels loaded at this port for Europe, during the harvest year ending June 30, 1882, were owned at San Francisco. That for said period of 12 months the freight paid on exports to Europe alone, hy sea, amounted to $16,069,789, and that the aggregate of inward and outward freights in the foreign trade to and from all ports on this coast must be not far from $25,000,000 annually, the proportion whereof earned hy vessels owned at American Pacific ports is an insignificant fraction of the whole. That the present lamentable decay of the American merchant marine in the foreign trade, has been entirely due to the failure of our Government to change the laws to suit the changing exigencies of modern progress, while other nations, especially England, have always given close attention to every detail of this subject, and therefore, by the substitution of iron and steel for wood, of steam for sail, by exemption from taxation, hy Government employment as mail carriers, and by the use of every means calculated to improve and cheapen transportation by sea, they have underbid us in every port and on every sea, so that in another decade, unless Congress comes intelligently to our relief, they will have completely excluded the American flag from the foreign trade everywhere; and while wooden ships can yet be built in the United States as cheaply as in foreign countries, the world now demands ships of iron and steel, hut Americans are prevented by the tariff from constructing such vessels, save at a cost so much greater than those of England as to confine their building to the coasting trade, in which they are protected from foreign competition; that the high tariff of the United States, therefore makes the business of iron or steel ship building for the foreign trade impossible.

The memorialists specially pray for the repeal of the last clause of Sec. 4131 of the Revised Statutes. "And officers of vessels of the United States shall in all cases he citizens of the United States" Repeal all sections or parts of sections numbered 4561, 4580, 4581, 4582, 4583, 4584, 4600, that provide for the payment of three months' or one month's extra pay to seamen when discharged in a foreign port, and substitute therefor the statute, which is now the law of Great Britain relating to the same business. Abolish all the fees of United States Consular officers now collected from shipping, and make good any resulting deficiency in their compensation by regular salaries. Allow a rebate of the tonnage tax of 30 cents per ton on each 300 tons of the vessel's register, for which no American apprentice shall be carried in the foreign trade, and compel all vessels in the coasting trade to carry at least one apprentice to every 300 tons of her enrollment. Abolish the laws obliging masters to return seamen to the American port of shipment, and to allow crews of any nationality to he shipped anywhere on time or hy the voyage. Make it a penal offence to demand or pay advance wages to seamen in any American port, or any bonds for shipping seamen, and that all such payments shall he void in law in final settlements with seamen. Enforce this against foreign vessels by requiring the Collector to refuse a clearance in case of its violation. Allow all provisions, stores and supplies used or consumed on board vessels where such vessels are bound upon a voyage to any foreign port, to he taken out of bond free of duty. Declare all shipping engaged in the foreign trade to he under the protection of the United States, and therefore exempt from State and municipal taxation; establish a Bureau of Commerce with a Cabinet officer at its head, and with duties analogous to those of the British Board of Trade. Liberal compensation for postal service by established American steamship lines, as is the policy of our commercial competitors.

The Public Lands.

The gist of the third topic was stated by the chairman to lie in the fact that a pre-emptor could not enter upon lands already inclosed; that public lands must he unoccupied by any one before the actual settler can enter on it.

Captain Blanding, from the State Immigration Bureau, addressed the Board on this question. He said we want a large population. He contrasted the population and area of the New England States with that of California, and showed how population is the first element of political power. The difficulty to get anti-Chinese legislation, he instanced as one of the benefits to he had from political power. He said the misrepresentation of the land agents of the northwestern States kept all hut 3,000 of the 400,000 and odd immigrants, who landed in New York from coming to this State. But a more serious obstacle than this must he removed, for the United States Supreme Court has decided that if lands were fenced, although they might be part of the public domain surveyed for entry, the pre-emptor could not legally settle on them. The Immigration Bureau, partly supported hy voluntary contributions, and in part hy the Railroad Company, had discovered that California has 43,795,000 acres of public lands, half of it suitable for agricultural purposes—a country equal to Indiana, whose population is a million of people. There is now surveyed and open to pre-emption, in this State 14,537,000 acres. The hills to right the evil in the matter of a settlement upon lands already inclosed, were still pending in Congress.

Minerals Near Pike's Peak.

In a communication to the *American Journal of Science*, by Whitman Cross and W. F. Hillebrand, of the U. S. Geological Survey, they say: The region about Pike's peak, in El Paso county, Colorado, has, within the past few years, become well known to mineralogists the world over through the large and perfect crystals of Amazon stone (microcline), which have found their way into almost every collection of importance in Europe, as well as in America. Other minerals, for the most part associated with the Amazon stone in occurrence, have also come into circulation to a less extent. The following minerals have been announced from this region, and are all authentic, viz., microcline, albite, biotite, quartz (smoky and olear), fluorite, columbite, gothite, hematite and limonite (pseudomorph after siderite), alfvedsonite, astrophyllite and zircon.

With but one or two exceptions the minerals named occur in "cavities" or "pockets" in granite, and although large quantities of some of the species have been found, there is scarcely a mineral locality which, at first sight, seems more unpromising than this. The coarse reddish granite of the district disintegrates rapidly through the action of the weather into a coarse, gravel-like mass, and many of the mountain slopes are made of such material, lying at a very steep angle, with solid rock projecting through it here and there. On finding fragments of crystals in the debris, the prospector for minerals, with pick and shovel in hand, endeavors to find the original cavity from which the fragments came. The "cavities" are very irregular in shape and size, and yield varying quantities of crystals. A single cavity has been known to yield more than a ton of crystallized specimens. All so far discovered have been on the surface. That a direct connection exists between the tendency of the granite to disintegrate so readily, the formation of the cavities, and the deposition of these various minerals in them, can hardly he doubted.

Quite recently several occurrences of minerals, new to this region, have come to our notice, and are thought worthy of description. We can add to the above list of minerals, topaz, phenacite, cryolite, thomsenolite, and others not yet fully determined. The phenacite and topaz were found about two years ago hy Mr. Thebaut, a prospector of Colorado Springs, associated with feldspar, smoky quartz and zircon, in one of the "pockets" described.

THE total shipments of bullion from Silver Reef, Utah, by Wells, Fargo & Co., for the month of September, aggregated $55,892.22.

Our Lumber Interests.

We have frequently alluded to the results of the census investigations into the extent and condition of Pacific coast forests. The subject is an interesting one, and there is now transmitted from Washington another forecast of results, somewhat different from those we have described before. Concerning California timber it says that the chief trees of the State are redwood, red fir, tide-water spruce, chestnut and red oak on the Coast range; and sugar pine, yellow pine and red fir on the Sierra Nevada. Any estimate of the actual amount of lumber standing in the State, except redwood, is not possible with the existing knowledge of the country. The principal lumber industry is confined to the redwood belt, on the line of the Central Pacific railroad, on both slopes of the Sierra Nevada, to points in Butte, Tehama and Mono counties, and in the San Bernardino mountains. The total product of the State for the census year was 304,795,000 ft. of lumber, 242,400,000 ft. of laths, 138,718,000 shingles, 2,063,000 staves, and 1,303,000 sets of barrel headings.

In Oregon the most valuable trees are in the order as set down: red fir, tide-water spruce, red cedar, hemlock, Port Orford cedar, white oak, sugar pine, chestnut, oak, larch and scrub pine. The principal lumber industry centers near Portland and Empire city. The product of the coast region for the census year was 151,443,000 ft. of lumber, 17,950,000 laths and 2,745,000 shingles. The product of the State east of the Cascade range was 25,798,000 ft. of lumber, 295,000 laths and 2,295,000 shingles.

Washington Territory, according to the *Bulletin*, is covered, west of the Cascade mountains, by the heaviest belt of forest growth in the United States. The most valuable trees in this region are red or yellow fir, covering about seven-tenths of the forest growth, red cedar, hemlock and tide-water spruce. East of the Cascade mountains the most valuable trees are red fir, yellow and white pine, larch, red cedar and hemlock. The principal lumber region is confined to the shores of Puget sound. The product of this region for the census year was 144,387,000 ft. of lumber, 6 550,000 laths, 710,000 shingles and 2,366,000 staves. The product of the coast outside of Puget sound region was 9,599,000 ft. of lumber and 200.000 shingles, and of the territory east of the Cascade range 6,190,000 ft. of lumber and 2,700,000 shingles.

The Mining Outlook in Montana.

Within the past two years Montana has been advertised in such a manner as to give a better idea of her exhaustless resources than ever before. The facts set forth from time to time in the "Mines and Mining" column of the *Independent* and other Territorial papers, particularly those of Butte, the many letters and collated items that have appeared in the New York *Mining Record*, and the display of our mining products at Denver, have brought our mineral wealth to the notice of capitalists, who, with the advent of railroads, will no longer hesitate to make personal examination of the advantages offered for judicious investment. There is no doubt that within the coming year there will he incursions of the men from the East with plethoric purses, who have hitherto only regarded Montana as an inaccessible region in the distant fastnesses of the great rocky herriers of the arid Northwest, and it is safe to say that they will see enough to astonish anyone who has not kept himself well informed concerning the progress making in the development of our vast mineral ranges. Still, we have only just begun to estimate the possibilities which may be realized hy systematic, intelligent and persistent efforts in a dozen districts in the Territory instead of one or two. One very common mistake is likely to be made by prospectors and owners of undeveloped properties. Instead of holding them at prices justified by their condition as mere prospects, they often demand for them the prices a mine ought to bring. Because a prospect looks well is not always an assurance that it will become profitable to work, and it is hardly just to demand that a purchaser shall pay the price of a mine, and then have to take the risk of finding one at last. Our great need is more development. If we are ready to demonstrate our ability to multiply the dollars of the investors who shall come here, and make them eager to avail themselves of the benefits that our need of their assistance may command, it will be because we have opened the door of our rocky treasure house sufficiently to convince them that we have an abundance of material which they may turn into "coin of the realm" with such appliances as their means can readily supply. Our increased output of bullion will this year add its substantial testimony to the growing importance of Montana, and such development as is compatible with the means at command, and the wise management of the properties already opened and supplied with facilities for active working will hasten the boom which is sure to come soon to this mountain land.—*Helena Independent.*

THE COST OF BOMBARDMENT.—The London *Daily News* says that at the bombardment of Alexandria, every round fired from 80-ton guns employed cost the Government $125. The cost of firing the 25 ton guns was $35. The 18-ton guns $25.25.

MECHANICAL PROGRESS.

Theory of Welding.

We noticed in a recent issue some late foreign investigations on the subject of the weldability of iron and steel. Prof. Ledebur's "Contributions to the Metallurgy of Iron," and Mr. Reiser's "Hardening of Steel in Theory and Practice," are both valuable contributions on a subject of great interest to our metal workers. The salient features of both papers are to be found in their agreement on those points which bear out the theories advanced by Chernoff, viz: That increased carbon percentage lowers the melting point, and decreases the weldability of both iron and steel, and that all foreign substances or elements which enter into the composition of merchant iron or steel are more or less active in the same direction. Prof. Ledebur's tabulated classification of iron into weldable and non-weldable irons, according to chemical composition is as follows, viz:

WELDABLE IRON.

	Per cent.
Carbon	0.14
Silicon	0 01
Sulphur	0.04
Phosphorus	0 11
Oxygen	0.05
Manganese	0.04
Copper	0.13
Cobalt or nickel	0.06
Total	0.58

NON-WELDABLE IRON.

	Per cent.
Carbon	0.22
Silicon	0 11
Sulphur	0.05
Phosphorus	0.13
Oxygen	0.05
Manganese	0.19
Copper	0.14
Cobalt or nickel	0.05
Total	0.96

From this classification Prof. Ledebur draws the conclusion that if, generally speaking, the percentage of foreign substance reaches a certain figure, iron ceases to be weldable. Mr. Reiser, whose experiments partly bear out the conclusion reached by Prof. Ledebur, having experimented with the product from ores essentially different from those considered by the Professor, naturally differs with the latter in regard to the influence of manganese, silicon and phosphorus. There is no doubt that both these gentlemen are careful, conscientious and intelligent experimenters, and their disagreements simply point to the conclusion hitherto frequently advanced in these pages, that in order to arrive at any satisfactory deductions in regard to the influence of these several elements upon the mechanical properties of iron and steel, it will be necessary to consider not only the percentage in the composition merely, but also the ratio their percentages bear to the carbon and to each other. While we are fully aware that this suggestion involves too wide a field of investigation for any single experimenter to cover, it is the only way in which positive results can be obtained. Even without concert of action in investigations constantly being made in this country and abroad, prompt publication of new results, compared with former tests, will do much toward the solution of this vexed question. We need hardly assure our readers of our deep interest in the subject, and our readiness to open our columns at all times to them for its discussion.—*The Iron Age.*

Facts about Steel.

Mr. William Metcalf, of the well-known firm of Miller, Metcalf & Parkin, of the Crescent Steel Works, Pittsburg, Pa., a practical mechanical engineer of many years' experience, concludes a paper read before the Engineers' Society of Pennsylvania with the following summary:

1. That a good soft heat is safe to use, if steel be immediately and thoroughly worked, for it is a fact that good steel will endure more pounding than iron.

2. If steel be left long in the fire it will lose its steely nature and the grain partake of the nature of cast iron. Steel should never be kept hot longer than is necessary to the work to be done.

3. Steel is entirely mercurial under the action of heat, and there must, of necessity, be no injurious internal strain created whenever two or more parts of the same piece are subjected to different temperatures.

4. It follows that when steel has been subjected to heat not absolutely uniform over the whole mass, careful annealing should be resorted to.

5. The change of volume due to a high degree of heat increases directly and rapidly with the quantity of carbon present, therefore high steel is more liable to dangerous internal strains than low steel, and great care should be exercised in the use of high steel.

6. Hot steel should always be put in a perfectly dry place of even temperature while cooling. A wet place in the floor might be sufficient to cause serious injury.

7. Never let anyone fool you with the statement that his steel possesses a peculiar property which enables it to be "restored" after being "burned." No more should you waste any money for nostrums for restoring burned steel, for "over-heated" steel can be restored by first bringing it to a red heat and allowing it to cool slowly. For "burned" steel, which is oxidized steel, there is only one way of restoration, and that is through the knobbling fire of the blast furnace.

8. Be careful not to overdo the annealing process. If carried too far, it does great harm, and is one of the commonest modes of destruction which the steel maker meets in his daily troubles. It is hard to induce the average worker in steel to believe that very little annealing is necessary, and that very little is really more efficacious than a great deal.

Finally, it is obvious that as steel is governed by certain and invariable laws in all of the changes mentioned, which laws are not yet so clearly defined as they should be nor as they will be. Nevertheless, the fact that there are such laws should give us confidence in the use of the material, because we may be sure of reaching reliable results by the proper observance of the laws. Therefore, there is no good reason why engineers should be afraid to use steel if they manipulate it intelligently.

Can Iron be Burned in Melting?

Mr. L. C. Jewett gives the following answer to the above question in an Eastern exchange:

I had the fortune a few days since to meet a foundryman who was in constant fear of getting his iron too hot. He claimed he was melting his iron just as hot as possible without burning—that if he melted better it would surely be burned. This is one of those strange delusions that sometimes trouble the minds of otherwise sensible people.

Now, I want to ask this man, and any others who may entertain the same views, what basis they have for their opinions?

A few years ago in a foundry in one of the Eastern States, the question arose: "Can iron be burned in melting in a cupola?" To settle this, test bars were cast at one heat, just coal enough being used, as my friend would claim, not to burn the iron. The next day test bars were cast of exactly the same dimensions and from the same mixture of iron, enough coal being used to melt the iron so hot that it was yellow, a fitful flame arising from it when in a dry ladle. The bars from the two heats were afterwards tested in a testing machine, when it was found that the bars cast from the hot iron were more than nine per cent. stronger than those cast from the iron which was said to be just as hot as it could be made without being burned.

Now for the reason: It is generally the case that in putting up iron for ordinary machinery castings, two, three, four or perhaps five kinds and quantities of iron are used. It is of the utmost importance, especially for such castings as cylinders, steam-chests, cylinder-heads and finished work generally, that the castings be homogenous.

When iron melts in a cupola it is essentially different from the melting of ice in water. The iron gets soft till it falls in pieces from the pig, and these pieces into still smaller pieces and the liquid condition is assumed, which means the separation of the molecules that were united to form the solid iron. Now, the hotter the iron gets, the more complete the separation of the molecules of each particular brand, and the more readily they will mix when they come together in the bottom of the cupola. As soon as the disintegrated pig gets hot enough to liquify it don't stop long enough in one place until it gets to the bottom of the cupola, and any additional heat it receives must be imparted in the transit from the melting point to the bottom.

It is not claimed that too much fuel cannot be used in a cupola. On the contrary, a surplus over and above that required to melt hot liquid iron may be used, which means an extravagant use of fuel. It has no effect on the quality of the melted iron, but it has the effect to make the cupola melt slow, and enough fuel may be put in a cupola to absolutely prevent melting. In stove-plate foundries, iron is generally melted much hotter than in machinery foundaries, and I have always observed that in foundaries where the iron is melted hot the average of the work is much better, and the percentage of poor castings much less, than where so much caution is exercised to prevent burning the iron in melting.

ON THE EFFECTS OF COMPRESSION ON THE HARDNESS OF STEEL.—Some interesting experiments have recently been made at the iron works of St. Jaques, at Montlucon, France, confirmatory of the results already reported by M. Darnos to the effect that compressed steel showed a greater degree of hardness than that metal produced without compression. In the experiments above alluded to, further and confirmatory results have been obtained. Steels have been analyzed, compressed and uncompressed, and containing different proportions of carbon. The proportion of combined carbon, as regards the total carbon, has always been found to be greater in the compressed than in the non-compressed steels. In some experiments made at St. Jaques on elongated shot, the samples being taken from four different points of depth, the results showed a mean of .585% of combined carbon in the compressed shot, while but .49% was found in the uncompressed. The same results, however, were obtained by sudden cooling in the ordinary process of hardening. Hence, it is inferred that compression produces the same physical effects in steel that tempering does in the ordinary manner of hardening.

SCIENTIFIC PROGRESS.

The Atomic Weight of Carbon.

The atomic weight of carbon has recently been redetermined by Mr. Roscoe according to the method employed by Dumas and Stas, consisting in the direct combustion of pure carbon, or, in other words, diamond. Diamonds from South Africa were used, and were placed in a tarred platinum boat placed in a glazed tube of Berlin porcelain, which was heated in a charcoal fire, and through which carefully purified oxygen was conducted. The products of combustion were passed (1) through a U-tube containing pumice moistened with sulphuric acid; (2) through two series of Geissler Liebig potash bulbs containing potash solution; (3) through three U-tubes containing pumice wet with a solution of caustic potash and (4) through two small U-tubes containing pumice and sulphuric acid. Six separate experiments were made. In the first, six small transparent stones of a pale yellow color were used; in the second, eight small dark stones; in the third, one large dark stone; in the fourth, four dark stones; in the fifth, four colorless stones, and in the sixth a piece of the black diamond known as carbonado. Assuming Stas' atomic weight for oxygen 15.96, the values obtained for carbon in the six experiments were as follows: 11.970, 11 978. 11.970, 11.976, 11.966, 11.995; mean, 11.9757. The mean value obtained by Dumas and Stas in 1840 is 11.9708. With the exception of the sixth experiment, in which the black variety of carbon was used, the hydrogen obtained did not exceed as a mean one seven-thousandth part of the weight of the diamond, and was probably derived from moisture in the apparatus. In presenting this memoir to the Academy, Domas called attention to the fact that if the atomic weight of oxygen be assumed as 16 that of carbon is 12 002, or within one-six-thousandth of a whole number.

A NEW NORTH AMERICAN ROSE.—Dr. George Eogelmann describes, in the *Bulletin of the Torrey Botanical Club*, a new species of rose that appears to present peculiar botanical and horticultural features. It was discovered by a party of botanists, consisting of Dr. Parry and Messrs. M. E. Jones and C. G. Pringle, while they were riding along a road skirting the shores of All Saints' bay, in Lower California. Forming, as it did, a most conspicuous and agreeable feature in the arid landscape, with its finely-divided foliage and showy pink or white flowers, it at once attracted the attention of the whole party. It has been named *Rosa minutifolia* by Dr. Eogelmann, who describes it as "a most striking and lovely species, distinguished from all other roses by its minute deeply-incised leaflets." The species is quite peculiar among its American congeners, and even among the roses of the old world, so that it is difficult to determine its true position. As seeds have recently been collected, we may hope to soon see the plant in cultivation.

SUPPOSED SUBTERRANEAN DRAINAGE OF THE INTERIOR OF AUSTRALIA.—In a paper in the *Journal* of the Royal Society of N. S. Wales, Vol. XV, 1882, entitled, "Notes of a Journey on the Darling," by Mr. W. E. Abbott, the author refers to the observations of Mr. Russell, which seem to prove that the amount of water received by precipitation over the watershed of the Darling much exceeds that which is carried off by the Darling and by evaporation, and he inclines to the opinion expressed by Mr. Russell, that there is an underground drainage system wholly distinct and different in direction from the surface drainage. The underground water would probably take a course to the southwest, and he suggests that this may have been the course of a more ancient river system. Some evidence with regard to such subterranean waters is presented from wells which have been sunk in the vicinity of the Darling, and whose flow seems to be independent of variations in that river.

INTERESTING EXPERIMENTS.—Some important experiments are about to be made in Cleveland, Ohio, to determine more accurately than ever before the velocity of light. The experiments will be conducted under the supervision of Prof. Albert A. Michelson, and extensive preparations have been made to obtain accurate results. The work will undoubtedly be closely watched by scientists interested in the subject, and as the velocity of light has an important bearing upon astronomical calculations, the experiments, if faithfully carried out, will be of considerable value.

A NEW PREVENTIVE FOR SLIPPING.—A European engineer, C. Heinrich, has invented a new apparatus, instead of the sand box now in use, for preventing locomotive wheels from slipping. It consists of a narrow tube, running from the hot water reservoir to the drivers, so that a small jet of hot water can be played upon the track, cleaning and drying the track at the same time, thereby giving the drivers their full power to propel the train. It has been used with most satisfactory results on the Motan road, of Reschetza, Hungary.

A GRAIN of iron may be divided into four million parts, and gold may be beaten so fine that it will take 1,360,000 leaves to make an inch in thickness.

The Vapors of Metals.

M. Eugene Demarcay has recently obtained volatilization at much lower temperatures by diminishing the pressure of the gas by which they are surrounded. His apparatus consists of a crystal tube 12 centimeters in diameter, containing the metal, and closed at its extremities. The heating is effected by vapors of sulphur, mercury, aniline, water, and other substances, giving temperatures ranging from 440° Cent. to 100° Cent. The vacuum is obtained by a Sprengel pump, and the tube is then heated in the vapors mentioned, at the same time that the pump is worked. A fine U tube, which enters the crystal tube until its bend is about two centimeters from the piece of metal, is traversed by a current of cold water, and serves to condense the volatilized metal. When the heat is applied a considerable quantity of vapor is given off, and this condenses rapidly on the bend of the cold water pipe, forming a dark deposit, which in time acquires a metallic tinge. Cadmium, zinc, antimony, bismuth, lead and tin have been volatilized in this way, at temperatures of 160° Cent., 184° Cent., 292° (antimony and bismuth), and 360° Cent. (lead and tin) respectively. At higher temperatures the deposits are more abundant; but M. Demarcay has not proved any volatilization at inferior temperatures to these given. He does not doubt, however, that volatilization, at lower temperatures, does exist; but it is masked by the formation of a thin layer of suboxide of a deep color, which is less voletile than the metal itself. In such cases, the metallic sublimation begins after this protective skin is broken. A very fine sample of vaporized gold attracted much attention at the microscopical reception, given at Harmon Seminary, Berkeley, on the 14th inst. It was collected from the fine of an assay-office furnace in San Francisco; shown under a small power, it presented a mass of exceedingly fine globules.

THE ELECTRICITY OF FLAMES.—A valuable contribution to the subject of the electricity of flames has been lately made by Messrs. Elster & Geitel. The discrepancies in results previously obtained are attributed largely to the fact that the behavior of the layer of air immediately outside of the flame was disregarded. The gentleman mentioned used a Thompson quadrant electrometer for measuring, and found the supposed longitudinal polarization of a flame merely apparent, and due to unequal insertion of the wires used as electrodes. They found, on the other hand, that a flame is strongly polarized in cross section, and an electrode in the air about the flame is always positive to the one in the flame. The theory adopted by the experimenters is as follows: By the process of combustion, free electricity is not produced in the flame, but the flame gases and the air envelope have the property of exciting, like an electrolyte, metals or liquids in contact with them. To this electrolytic excitement is added a thermo-electric, due to the incandescent state of the electrodes. The amount and the nature of the electrolytic excitement is independent of the size of the flame, but depends on the nature, surface, condition and glow of the electrodes, and on the nature of the burning gases. It was remarked that flames may be combined in series, like galvanic elements, so as to form a "flame" battery.

THE RESISTANCE OF THE AIR TO THE MOTION OF BULLETS IN GUNS.—Prof. Colladon, of Geneva, recently described a curious experiment showing the resistance of the air under certain circumstances to the motion of bullets in guns. He charged the hollow iron breech of an air-gun serving as a reservoir with compressed air, and, having screwed up the gun, introduced a round lead ball, running freely, but nearly filling the bore; then, placing the gun in a vertical position, he seized the upper end and pressed his thumb vigorously on the mouth. The gun was then "fired" by an assistant; the thumb remained in position, and the ball was heard to fall back in the bore. Thereupon, after recharging the breech and with the same ball he shot the latter at a pine board about four inches thick on a pane of glass, and it passed through. The experiment, M. Colladon says, is without danger if the operator is quite sure of the strength of his thumb, if the gun is more than 32 inches long, and if the ball is spherical and nearly fills the gun, in which it must act like a piston.

THE ATOMIC WEIGHT OF URANIUM.—The "Lerichte der Deutschen Chemischen Gesellschaft" states that Clemens Zimmerman has prepared metallic uranium, and determined some of its properties. Its specific gravity was found to be 18.685, and its specific heat between 99° and 0° is .02,765. The latter number multiplied by 240 gives a product of 6.64, which agrees with the mean atomic heat indicated by Dulong and Petit's law. The controversy between the values 120, 180 and 240 for the atomic weight of uranium is thus settled in favor of the highest.

TO MEASURE THE VELOCITY OF TRAINS.—Among the instruments described during the late meeting of the British Association was one exhibited by Sir F. Bramwell, employed for ascertaining the velocity of trains and the efficiency of brakes. With this apparatus it was found that a train weighing 125 tons ran five miles five yards after steam was shut off while traveling at a speed of 45 miles an hour. The line was level and the day calm.

Mining Share Market.

Our stock tables show no unusual fluctuations. On Tuesday there was quite a little spurt. On Wednesday morning again the market was strong, but it fell off once more. The Chollar drift, of which much was expected, has thus far shown nothing of value. The material filling the vein at the 2,600 level, where passed through hy the west drift, consists prinoipally of porphyry and clay. Mingled with this are lumps of boulders of quartz containing no metal. The finding of the quartz in this shaps, instead of in streaks and stringers, indicates the end, the giving out, of the body of quartz encountered 200 ft. ahovs. It is the tail end. It is just like a stream of falling water whioh breaks into drops near the end of its course, though starting off in a solid sheet. Although these boulders indicate the end of the body of quartz above, they also indicate the beginning of a new body below. They show a break in the vein. Bslow, these boulders will again come in ssams and feeders, and presently a new deposit of quartz and ore, and the new body may prove better than that found above. When cut through above the quartz gave good assays, and there may yet he found to he a paying deposit of ore of considerable sizs hstwesn the point where these assays were obtaiued and the drift, some 200 ft. below.

The Hale & Norcross folks have started a drift from the 2600 level of the Chollar-Norcross-Savage shaft, and will push it foward as rapidly as possihle, to a point where it will he connected with the winzs down from the 2400 level. This winzs is now down a little below the 2500 level; therefore, less than 100 ft. of ground remains to he cnt through in order to secure a oonnection and thorough ventilation. By making an upraise from the drift and hy sinking ahove the connection can soon he made. Once a circulation of air has been obtained, explorations may he made, and something definite ascertained in regard to the character of the formation on the 2600 level, now cut into at hnt a single point.

THE MINING INDUSTRY.—The Boston *Traveller* in a recent issue avers that at no time for three years has the outlook for the legitimate mining indnstry been more promising than at the present time. The nnmher of "wildcat" schemes on the market has been greatly reduced during the past six months, and now an enterprise that has not the very hest of management hack of it, and that cannot stand the most thorough investigation at the hands of the public, has little chance of success either in the New York or Boston mar ets. The "hooming" processs is practically a tning of the past; the public want actual facts, and will take nothing else. Daped already many times hy large promises and small fulfillments, they inve t now with great caution in any and everything pertaining to mines. But in this industry, as in all other, the good properties hold their own, while the "wildcat" schemes are daily sinking out of sight in a way that is most gratifying to every honest man. The reports from all the western mining districts are at present of a most encouraging character, and if manipulation is now only kept out of the market, and the speculation is not allowed to develop into a craze, the value of all the first-class mining securities will, without douht, hs soon permanently advanced to a hasis considerably higher than the present one.

News in Brief.

CHICAGO is rejoicing over the arrival of a band of Oregon sheep.

THE commission of over 350 postmasters will expire at the next session of Congress.

THE average death rate from yellow fever in Mien and Camargo, Mexioo, is 11 daily.

THE British ship *Bremen* from Liverpool went ashore on Farallone island, and is a total loss.

FLOATING ics has caused a snspension of navigation on the Volga and Kama rivers in Russia.

INGERSOLL still oharges the Government with attempting to brihe the jury in the Star Route oases.

THE Vanderbilt party's spscial train ran at the rate of 59 miles an hour from Burlington to Chicago.

THE Committee on the Channel Tunnel have made a report nnfavorable to the pr jsot, as dangerous to Eogland.

A FARMERS' ditch company of Orangethorpe has been incorporated in Los Angeles for distrihnting water for agricultural purposes.

THE Australian cricket team took £11,000 hard cash with it from England, as the result of its professional tonr through that country.

THE retirement from active service, by the operation of the law, of Major-General McDowell, October 15th, is officially announced to the army.

FROM three grapevines growing in a Washington street vineyard st Los Angeles, 360 lbs. of grapes were picked, and the vines were not stripped.

FARMERS on the Swinomish, W. T., are puzzled over the appearanoe of a short, thiok, yellowish worm which has been operating among the grain this season, destroying the roots when green.

SHINGLES are in suoh demand at Seattle, W. T., and have risen so in price that an importation of 250,000 is heing made from California, the only importation in at least a quarter of a century.

THE National Dress Society of Great Britain offers a prize of £30 for "the design of a female garment combining ease, elegance, comfort and health." The "divided skirt" has been condemned.

AFTER a thorough discussion, the Congress of Jurists at Cassell has unanimously answered the imnortant and much-dehated question, "Is the State hound to indemnify condemned persons when acquitted on a second trial?" in the affirmative.

OPERATIONS OF THE MINTS.—The report of the Director of the Mint presents in detail the operations of the Mints and Assay offices dnring the fisoal year ended June 30, 1882. The imports of foreign gold coin and hullion the first half of the year were $30,100,230 greater, hut during the last half $28,311,047 less than the exports, the net gain of the year hsing only $1,789,183. T tal amonnt of gold deposited, $66,756,653, which was $74,000,000 less than the preceding year, whils the silver purchased for coinage and deposited for hars was about $3,000,000 greater, and amounted to $33,720,491. Total coinage, 11.266,003 pieces, valued at $89,413,447, nearly $11,000 more than in any previons year. The silver coinage consisted of 27,772,075 silver dollars, and $11,313 in fractional coin.

TO THE OLD HOME.—Herman F. Dexter, cashier for Dewey & Co., who has been constantly connected with the office for years, started on a visit to his parents and friends in Orange, Mass., on Tussday last. He received the worthy testimonial of a fine gold watch, inscibed "From Dswsy & Co. and their associates."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

KELLY.—Amador *Ledger*, Oct. 12: Both mine and mill are again in full blast, giving employment to a force of 24 men. The mill has been running to its full capacity of 10 stamps for over a week. Mr. Walton, the superintendent, informs us that a 7-ft ledge of good quartz exists in the tunnel, and that the prospects are very encouraging.

MISCELLANEOUS.—The shaft of the Jackson mine has beeo repalred, and work is now moving along smoothly. .....The Moore mill was started up Wednesday, or, rather, the water was turned into the pipe for the purpose of starting. The water-wheel, however, did not act satisfactorily. Either the pressure is not sufficient, or the nozzle too small. At any rate, the power is not enough to run the 10 stamps.

CALAVERAS.

TUNNEL.—*Mountain Echo*, Oct. 14: The tunnel now being run by Lindsay & Co. is supposed to he witbin 10 or 15 ft of the old works. This is, of course, to a certain extent, guess work, as the company has not yet takeo pains to ascertain the exact distance. This mine is different in formatiou from soything in this section, rich deposits of gold being frequently found in the slate, whicb is of a dark brown color. We were shown a specimen of gold, taken from the mine recently, which was probably worth from $10 to $15. There is in this mine a vein of quartz about 6 inches in width. No gold is visible on the surface of the ore, and yet it is worth from $1.50 to $2 a pound.

EL DORADO.

CEDERSURG.—Georgetown *Gazette*, Oct. 14: The old Cederburg North mine, at Greenwood, has recently been reorganized by a San Francisco company, under the name of the "New El Dorado Gold mining company," W. N. Martin, M. D., President and managing director. Preparations have already commenced to put the mine in first-class condition for extensive hydraulicing. Fifteeo men have already been secured to begin work next week. New ditches, flumes and reservoirs will be constructed. Valuable flat pieces of quartz, from a few dollars to thousands of dollars in value, have been found on the hillside from time to time, and as the line of the famous old Cederburg lode is believed to extend into this hill, the enterprising new company has determined to unearth its hiding place by hydraulicing. We have faith in the new enterprise.

INYO.

THE MONTEZUMA.—Inyo *Independent*, Oct. 14: With a force of some 16 men altogether, Supt. Griswold is now making good progress with the work of getting the new furnace at the Montezuma mine in shape. Capt. A. M. Stetson, one of the owners, is in charge as engineer and machinist, with Billy Hedge. Mr. S. D. Woodhull is well fixed with a complete assay office, while the company has all the usual buildings for quarters. Mr. and Mrs. Saylor, of Big Pine, have charge of the boarding house. Grading for the furnace is about complete, and much of the machinery will be put in place next week. The ore cbute from the mine down to the road is finished. It is simply a box 16x12 inches square and 450 ft long.

STRUCK IT.—A brief note from Lookout states that Frank Fitzgerald is jubilant over his prospects wi h the Madcock property, having just "struck it rich" in the Sismark mine. We hope for some particulars next week.

MONO.

BODIE.—*Free Press*, Oct. 17: All the mines and mills now running in this district have made their preparations for the winter, in the way of getting in wood, timbers, etc. The Noonday mill is the last to be supplied, but it has an order in with the railroad company for 6,000 cords of wood, which will be put in as rapidly as possible. In a general way it may be said that the mining companies and the town are in as good condition for a long, hard winter as they ever have been. The Standard shipments this week amounted to $20,153 28, and those of the Bodie to $10,547.57. The pulp assays in the latter ran up last week to $101.88 per ton. Standard is still crosscutting east on the 1000 and 700 levels, and the east crosscut from the Lent shaft is in 274 ft. Red Cloud has again commenced sinking, and the shaft is now 810 ft deep. The Tioga shaft is down 1,077 ft. Ore is still working in rich ore from the winze below the 620 and 714 levels. The various mills are all running steadily.

ORO.—The south lateral drift from bottom of the north winze, 530 level, was extended and timbered 4 ft during the week; total, 33 ft. The ore vein is without change. A small flow of water is coming from a new ruby ore streak, or the hanging-wall clay; work in the face was discontinued and stoping ore commenced. The vein holds its width and quality as the stope goes up on it. Fifteen carloads of $50-ore have been taken from this stope, the necessity of hoisting water delaying progress very materially.

BODIE CON.—There were 160 tons of ore sent to the mill during the week ending the 14th inst.; 115,098 were crusbed; average value of pulp, $101.88. The amount of bullion shipped was $10 547.67. The amount of ore hoisted from the mine was 220 carloads; 25 carloads from the fifth level and 201 carloads from the workings between the 600 and 750 levels. In the workings on the rich vein from winze No. 17 the combined length of the north and south gangways, on the 670 level, is 144 ft. At the bottom of the winze the total length of the drift is 102 ft. The workings in the stopes there from look fine and are yielding very rich ore.

STANDARD CON.—There was extracted and shipped to the mill 1,523 tons of ore; received 4,450 ounces of crude bullion and shipped to the company $20,163.28. East crosscut, 1000 level, has been advanced, since last report, 17 ft; total length, 1,018 ft, with no change to note in the character of the rock cut through.

TIOGA CON.—The influx of water increased slightly during the week, but not in sufficient quantities to retard progress in sinking.

RED CLOUD CON.—On the 11th inst. sinking the shaft was resumed, since which time it has been sunk 7 ft, making a total depth of 810 ft. The pumps are making about 6 strokes per minute.

NEVADA.

MOONT AUBURN MINE.—Nevada *Herald*, Oct. 14: Work at this mine will he commenced again in a few days. M. C. Taylor, of Grass Valley, has the contract for putting up a 10-stamp mill, and the work of erecting the same is expected to begin soon. The work heretofore done on the Mount Auburn has demonstrated the existence there of a good vein of ore, and the company propose now to begin operations upon a thorough, systematic plan.

PLUMAS.

THE CRESCENT.—Plumas *National*, Oct. 11: The new departure at Crescent Mills makes the old town look much more healthy, and the indications are plenty that the Davis strike is a good one and will prove very valuable to the company. We have a piece of rock from the drifts on Tuesday, which is filled with free gold, and Mr. Garland, who brought it, tells us that quite a large quantity of magnificent ore is now in sight and on the dump. Fifteen men are now employed, and arrangements are being made to start up 15 stamps of the Crescent mill, and they will soon he pounding out the gold. The run of rock from the Crescent, in the Batchelder mill, proved it to be first-class, 56 tons being worked and the result being about $1,200. It is thought that when the proper arrangements are made, the rock will yield $30 per ton. Mr. Davis is crowding the work along, and will soon have a dividend for the new owners.

PLUMAS MINES.—Butte *Record*, Oct. 14: A gentleman well known in this city, formerly in business here, came

down from Greenville, Plumas county, yesterday, where he has been for nearly a year past in the mines. He says that he sunk several thousand dollars in a hole up there, besides tolling like a slave, and old not make a cent. Last week he quit work and abandoned his mine entirely. None of the mines, he said, are paying now, having all been worked out. The Green Mountain mine, which is so widely known, as being one of the best claims in the State, has not produced enough metal for several months to pay the workmen, who are quitting without any prospects of ever getting their wages. He also said that the mining region had not prospered since the death of H. C. Bidwell, who was always enterprising and opening new mines. That old miner had abrewdness, and handled the claims of the people in such a manner that they always paid well. By his exertions, Eastern capitalists were persuaded to invest money in the Plumas county mines, and the country was kept lively and prosperous. The once famous Savercool mine is never heard of now. It was once claimed as being the richest quartz mine ever opened in the state, and thousands of dollars were spent in the purchase of new machinery, which is now said to be lying idle and allowed to rust. Once in a great while we hear of some lucky miner striking a good pocket, but, so far as the large mines are concerned, they are now counted as being worthless.

SIERRA.

THE PHŒNIX GRAVEL MINE.—*Tribune*, Oct. 14: John Lamey, an owner in the Phœnix mift claim, at Fir Cap, was in town Monday and gave us the following facts regarding the progress of work at that mine: The Phœnix was worked quite extensively in early days and very rich gravel taken out, it paying as high as $1,000 per carload. owing to bad management, the claim was abandoned. The present owners have the main tunnel in 2,400 ft, with bright prospects for soon striking gravel. They are confident that a channel, never discovered by the old companies, exists in the claim.

UNION MINE.—*Mountain Messenger*, Oct. 14: The old Union drift mine, at Gibsonville, is proving very rich. It was supposed by some to be worked out, but others thought not, and the result proves that it was not. For one day's washing, recently, $5,000 was realized. The Redding mine, owned by James De Noon, is also paying well—about $2.75 to the carload.

JIM CROW MINE.—Grass Valley *Union*, Oct. 14: The Jim Crow quartz mine, in Jim Crow canyon, Sierra county, which is being opened and worked by a Grass Valley company, is showing up quite encouragingly. Mr. John Collier, who is just down from the mine, brings very favorable accounts of the prospects.

NEVADA.

WASHOE DISTRICT.

CON. VIRGINIA.—*Enterprise*, Oct. 15: The joint California east drift on the 2700 level has been advanced 25 ft.

SIERRA NEVADA.—During the week the north lateral drift on the 2700 level was extended 32 ft, and the south lateral, on the same level, 10 ft.

CALIFORNIA.—The joint Con. Virginia east drift on the 2700 level has been advanced 25 ft. Are extracting ore from the croppings.

MEXICAN.—The tank station at the 3000 level of the joint Ophir winze has been completed and sinking has been resumed. The northwest drift on the 2100 level has been advanced 15 ft.

OPHIR.—The tank station at the 3000 level, in the joint Mexican winze, is completed, and sinking has been resumed. The main south drift on the 2100 level has been advanced 25 ft. During the week 55 tons of ore have been extracted from the croppings.

UNION CON.—On the 2700 level crossent No. 3, from the main lateral drift, has been advanced 22 ft. Sontb drift No. 2, on this level, has been advanced 20 ft.

CHOLLAR.—During the past week 100 ft have been added to the length of the drift west from the Cholla-Norcross-Savage shaft, 2000 station, making the total length from the shaft 500 ft. The material passed through was porphyry, clay and quartz. Nothing of value was found, the highest assay obtained being $1.90. This (Saturday) morning the face of the drift shows the black dyke that lies on the west wall, leaving no doubt that the drift has passed through the vein. Drifting west will be stopped this afternoon. Lateral drifts north and south will be commenced at a point some 400 ft west from the shaft. No water of any account has been encountered.

YELLOW JACKET.—Since the last weekly report the water in the mine has risen 12 inches, standing to-day about 1,152 ft above the level of the 3000 station. At the Winters shaft they are extracting about 20 tons of ore daily, from the second, third, fifth and sixth levels. On the Sagebrush level the clay met with in the north lateral drift is of such a swelling nature that they have been obliged to abandon 50 ft of the drift, and come back that distance from the face and turn towards the northwest to avoid the same. They have shipped 434 tons of ore to the Brunswick mill since last report.

BRISTOL DISTRICT.

THE CAMP.—Cor. Eureka *Sentinel*, Oct. 14: Bristol is situated 5 miles from the principal mines in its district. Foremost among them are the Tempest, Iron, May flower and Noonday, all of which have handsome ore showings.

THE TEMPEST.—The Tempest has $300,000 worth of ore in sight, ranging in value from $25 to $75 per ton. The depth attained is but 300 ft, and the chances are good for a great mine in the near future. The ore is more adapted to milling than smelting. Oilmer & Salishury are the lucky owners of this mine, as well as of the Iron. The latter has 4 ft of heavy lead ore, suitable for fluxing, going about $30 in silver and 60 lead. Work was stopped recently and the men knocked off, though active operations will soon be recommenced.

THE MAYFLOWER.—Of the Mayflower but little can be learned, the superintendent keeping remarkably close on anything pertaining to the business of his company. One thing is certain, and unfortunately, the miners were not paid their wages, and are naturally indignant. Being put off from month to month, they are becoming tired of the continual procrastination, and have filed liens on the mine. Yet those who worked in that property claim that it is looking well.

THE NOONDAY.—The Noonday, owned by Messrs. Barton, Howell & Wilson, looks better than for a long time back. Hopes are entertained of its ultimately proving one of the mainstays of the camp. First-class ore is taken out, some reaching very high figures.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Oct. 14: The advance made in the main drift on the fifth shaft level has been 17 ft, the face showing the same formation of favorable-looking sulphurets as last reported. Crosscut No. 1, on the same level, is in hard quartzito. The distance made for the week is 8 ft, the total length being 132 ft. The development made a few weeks since, in the western part of the second shaft level, has opened into 3 ft of yellow chloride, and promises well for the future. The stopes in the uprises from the first shaft level are looking well and producing considerable ore of a good grade. As the work progresses in the 10th level in opening the stopes, the outlook is very encouraging, and a fine body of ore of excellent grade has been developed at this point. The prospect below the last-mentioned level is not so favorable as last week. The main winze from the 10th level has been sunk 30 ft. It has passed entirely out of ore into hard working ground. As the ore body pitches to the north, it is probable that the work now in progress is not far enough in that direction. Therefore, a drift will be started at once for the bottom of this winze. About 70 tons of ore are being taken out daily and shipped to mill No. 2, which is running steadily and working well. The bullion shipments amounted to $20,516.84 for the week ending October 12th, and aggregate $25,973 on October account for the same date.

MOUNT DIABLO.—The south crosscut from the bottom of winze No. 1 has reached a length of 81 ft, and the east drift from the same winze is in 67 ft. Both of these drifts have been stopped for the present, so that drifts to the east and west can be commenced on the body of ore found some 40 ft above the bottom of this winze. The winze from the east drift on the second level shows about 6 inches of $40-ore that looks encouraging. The south crosscut from the Mount Diablo adit has advanced 15 ft during the week.

DOWNEYVILLE DISTRICT.

THE FURNACE.—Cor. Grantville *Bonanza*, Oct. 10: I have just returned from a visit to the furnaces. The new engine-room, handsomely painted and finished, seems fitter for a lady's boudoir than for the purpose to which it is dedicated. New machinery in every part; lights glittering everywhere.

EUREKA DISTRICT.

EUREKA TUNNEL.—Eureka *Sentinel*, Oct. 14: From 6 to 8 tons of ore per day is now the usual shipment from the Eureka tunnel. The ore averages over $100 per ton. Several stringers of ore have been neglected for some time past, owing to poor ventilation, but that difficulty having been removed, work will be resumed to-day on 5 of these stringers, and it is thought that the result will be a great increase in the ore production of the mine.

THE GREGORS & BERTRAND.—No report has recently been given of this mine, which is at present among the chief ore producers of the district, if, in fact, it is not producing more than any other mine. The mill is running smoothly now, in perfect order, and reducing 80 tons per day. Eight men are employed in the mine—but one shift—and they get out readily all the ore that the mammoth mills can reduce. The ore body is represented as being immense as far as explored, and of unknown extent in its limits. The indications are that it is a continuous mass from 20 ft below the surface to the 300 level, the lowest point yet reached. The 150 level is the main level from which the ore is extracted for reduction. The chamber excavated on this level is in a breast of ore 40 ft deep and 50 ft across, the body of ore still extending indefinitely beyond these lines. The ore is easily broken down, a keg of black powder bringing down between 40 and 50 tons at one blast. The average grade of the ore is about $40 per ton—that is, the great mass of it is of this value, although there is ore in bunches in the mine which assays upwards of $300, and in spots runs up into the thousands. The average assay of all the ore reduced up to this time is approximately $40 per ton. The dimensions of the ore body opened on the 150 level have become so great that the ore is hardly missed by the quantity removed at the present rate of excavation in a month. It is estimated that a cubic foot of the Geddes & Bertrand ore weighs about as much as the same volume of gravel 400 lbs. On this basis a body of ore measuring 10 ft every way would yield 200 tons, and the 50 by 40-ft chamber opened has turned out 5,000 tons. The cost of milling and mining is not to exceed $10 or $11 per ton. A perfectly safe estimate of the net yield above all expenses per ton on $40 ore is $25. At the present rate of reduction, 80 tons per day, this would bring into the company a net profit of $2 000 daily, or $60,000 per month; but say the net yield of ore after being reduced is only $20 per ton, this would foot up $48,000 per month. The mine cost Messrs. Gilmer & Salisbury $47,000, and the mill $250,000, in round numbers—$300,000 altogether. The bullion shipment for Septomber was $37,000. This month it will be upwards of $60,000. It is only lately that all the machinery has been got into perfect order, and the mill running smoothly under full beadway. In less than 6 months from date the mine will have paid all the expense of its original cost, as well as that of the splendid reduction works, all of which, mine and works, will then be clear profit to the enterprising proprietors.

JACK RABBIT DISTRICT.

CHANGE.—Pioche *Record*, Oct. 10: The Day furnace will suspend operations on or about the 10th, the hoisting engine at the mine not being of sufficient capacity to raise the quantity of ore necessary to keep the furnace running steadily. The heavy engine, boiler, etc., of the Bi laide hoisting works, after undergoing a thorough state of repair by a competent engineer, will be conveyed to the Day mine, in Jack Rabbit district, and there utilized for hoisting, in place of the light donkey engine, etc., which will be removed. It is estimated that to complete the necessary change a period of 60 days will be consumed.

LEWIS DISTRICT.

THE MINES.—Lewis *Herald*, October 14: The Morning Star mine is proving rich in gold. It has a 3-ft ledge that shows native gold. The company will build a mill soon. The Betty O'Neil is going down another hundred ft. The last level is good. They are putting up another boiler and are now fixing to handle the water. They will soon have their own mill. The Chloride is leased to parties who are taking out good ore.

SILVERADO DISTRICT.

NEW LIFE.—Eureka *Sentinel*, Oct. 14: From Dick Berryman, who was in yesterday from Silverado mountain, we learn that there are indications of new life in the camp, the mines in that locality showing continual improvement as the work of development progresses. The Queen mine is looking healthy and is showing more ore in sight than at any one time since it was located. The owners are at present working on a four-foot vein of hard carbonate and galena ore that will assay from $300 to $500 per ton. It shows signs of permanence, and the boys are greatly encouraged. Lou Dibber is putting in good licks on the Silver Globe. The tunnel has been run in and connection made between it and the old surface works, which are being cleared of all the waste that has accumulated. A nice vein of hard quartz and carbonate ore is exposed, upon which the work of extraction will immediately be commenced. John Potter is running his new tunnel, and is much pleased with the indications presented. The Diagonal mine is looking well and proving to be a property of greater value than ever. The Berryman boys and others are extracting ore at present from two places, both new discoveries. Dick says he has been prospecting a little on the Silver Plum, also on the Leonard Courtney, series, that were located last summer, and is satisfied that nobody will lose money by investing their dollars in those diggings.

WARD DISTRICT.

WILL START UP.—White Pine *News*, Oct. 14: Parties in from Ward tell us that it is now fully determined upon by the Martin White company to start up their mill on the 1st of January next. It is estimated they have high-grade ore enough to run for a year at least.

WHITE PINE DISTRICT.

HAMILTON PROSPECTS.—White Pine *News*, Oct. 14: During our brief visit to Hamilton last week, we had not the time we should have wished to look around and converse with its people. There seems to be a strong feeling of hopefulness among our neighbors, and they think the dawn of a brighter day is breaking upon them. Mr. E. N. Robinson was pushing work on the "Smokey Mill," and expected to drop stamps by the 20th at latest. He informed us that work on his mines was progressing satisfactorily, and all were yielding ore of good quality. Capt. Drake, of the Eberhardt tunnel, also informed us that the prospects of that once famous property were such as to inspire hope. Sometimes he came across bunches of good ore in the lowest depths, though so far they did not prove to be permanent or lead to large bodies. The Captain thinks there are yet undiscovered bonanzas in Treasure Hill, and we believe if they are there the Captain will find them. It made the old standbye feel good to point to Mr. Robinson's quartz teams as they came down from the hill with ore for the mill. Indeed, so confident are our neighbors of better times to come in the near future, that they hinted that they might soon be able to offer such inducements as would lead the *News* to return to its old love and renew its allegiance to its Alma Mater.

ARIZONA.

BIG BUG.—Bennett *Courier*, October 12: Judge John A. Rush was recently in Big Bug district, on mining business. He was accompanied by a gentleman who desired to see properties belonging to M. Wormser, of Phœnix. The Judge, himself, has a few good mines in the district. His limited stay prevented the accumulation by him of much mining information, but he learned that development work in the upper portion of the district is progressing favorably. The Lynx creek smelter was running out bullion from Silver Belt ore.....The Dosoris expressman tells us that a great many miners are working in the Dosoris, Blue Bird and other claims of the camp.....John L. Taylor recently finished assessment work on 3 or 4 claims in Bradshaw and Peck districts. We asked him if he had examined the Tiger mine. He said he had, and that it looked good... Several more car-loads of ore are ready to be shipped from the Black Warrior mine, Peck district... Messrs. James Campbell and Chief Rondebush have just arrived from the East. They are interested in Castle creek and Black canyon districts. They are prepared to put a great deal of money into mines and machinery.

TOMBSTONE.—*Republican*, October 14: While we can report nothing strange or startling this week, still we can confidently say that the mining outlook in this district was never better. Never before in the history of the camp was work so general and uninterrupted, and never was faith so vigorous and strong in the perpetuity and wealth of the mines. There are not less than 50 mines and prospects being worked in the district at present, and that is in itself a pretty safe indication of the warm undercurrent of industry that flows beneath our seeming apathy. The mines of Contention hill are running along about as usual. The customary quantity of ore is being hauled to the surface and shipped to the mill. In the western portion of the district things are unusually lively. What were mere prospect holes a few months ago are now full-fledged mines yielding from 10 to 20 tons of ore daily, with several underground delvers in stopes, shafts, drifts and crosscuts. There is hardly a doubt but that the western part of the district will rival Contention hill ere six months roll by.

AROUND PRESCOTT.—*Courier*, October 14: Dave Grubb's Cash mine is about ¾ of a mile from the bridge in Hassayampa district. The vein is about 2½ ft thick, rock rich in gold; 38 pounds of it have yielded $340.14; $60 in specimens have recently been taken out. Vein matter is from 7 to 8 ft thick. From a shallow shaft Mr. Grubb has 18 or 20 tons of ore on the dump. Grubb's silver ledges are among the richest in our pine-clad hills..... A few days ago, when Ed. W. Wells was at the Copper mountain mine, east of Prescott, they were down over 80 ft by shaft. Tunneling was also going on. Blocks of ore 1½ ft square, carrying 80 per cent. copper, were being taken out. A site for a smelter is already graded. It is near Hill's place, on the Agua Fria.... D. Hatz, who recently visited Turkey creek district, says that the Homesite mine is producing silver ore worth nearly $500 a ton.....The Bodie mine, Hassayampa district, is said to be a No. 1 property. Mr. Smith, President of the Bodie company, and the Secretary, Mr. Montgomery, are in New York, shipping a furnace, etc. There is in the mine a 400-ft tunnel; ore is to be seen anywhere in this tunnel, and it is estimated that the largest dump contains 700 tons of first-class ore.....Citizens of Prescott who yesterday went out to Groom and Walker districts returned home highly pleased with mines and mining out there. Also with the new road recently made a most as far as Lynx creek, mainly at the expense of George W. Curtis and W. N. Kelly.....The Wadleigh mine, in Walker, is said to be the biggest thing in the mountains.

COLORADO.

THE VULCAN.—Colorado *Miner*, Oct. 14: The Meyers boys have been working industriously the past few months on this valuable property, which they own in connection with Charles W. Pollard of this place. After running the Egau cross cut tunnel, some 400 ft above the Pay Rock main buildings, ahead till it cut the Vulcan, they drifted 50 ft westerly to the Daniel Peters lode, and about 300 ft easterly till the east breast was directly under and 150 ft below the shaft sunk 125 ft from the upper level. They will raise to the shaft and have in all, upon the lower level, a total depth of 350 ft from surface, all along this lower level is an ore veiu of black sulphuret and galena mineral, varying from a half inch to eight inches in widtb and running from 350 to 700 ounces. This shaft is also in ore the whole way. When connection is made the owners will have a very extensive body of rich ground opened up, and will begin shipments immediately.

THE Moline tunnel, which is located on Democrat mountain, in the gulch below the New Boston, Muscovite, Henry Ward Beecher and other prominent lodes, is being worked hy two shifts of men, who are using an Ingersoll drill, which is run by steam power. They are making from 80 to 85 ft per month. The work is well done, the tunnel is 8x8 ft in size, and is perfectly straight. It is now in 435 ft, and has crossed 3 undeveloped lodes. On the lines of the tunnel there are 32 lodes. The company is a strong one, having plenty of capital, and intend to drive through the mountain. The property is managed by Mr. Hartzell, who thoroughly understands his business. They are employing 9 men and 1 jack at present, the latter being used to pack wood for the engine.

IDAHO.

YANKEE FORK.—Cor Idaho *Messenger*, Oct. 14: The mines being worked are doing as well as ever. The marvelous richness of the Charles Dickens has long since ceased to astonish, for with the Dickens there seems to be nothing impossible, and it's a 2-ft vein of solid gold and silver should at any time be encountered, I doubt if it would excite any one here. I paid a visit to the mine recently. The new winze, about 900 ft in from the entrance of the tunnel, is down about 30 ft, and the ore is even richer than above. This gives a depth from surface of 300 ft, or over. The richest of the vein varies in width from 6 inches to 2 ft, and in this a seam or vein of solid metal is found 1 to 3 inches in width. Masses of wire silver and gold as large as a saucer are taken out daily. Then again it is found in curious shapes resembling filigree or ornamental work of silver and gold wire. All this deep wealth of the Charles Dickens promises another mill in our camp next season..... The Montana will be worked with a stronger force of men this winter than heretofore, and much shipping ore will be taken out and greater developments be made. Mr. Hooper resumes the superintendency, and Mr. Franklin goes this week to the States for the winter..... The Custer company is putting 10 more stamps in their mill, making 30 in all. The great promises of the company's mine require this additional crushing capacity..... The Tonto mine, on Mt. Estes, owned by Horace Dodge, James Burton and Aleck Klopfer, is to be worked this winter. In former days the Tonto had a very rich chimney of gold ore, and the owners propose to search for it deeper down..... Mr. Curtis Estes has found rich prospects in a gulch on the east side of Mt. Estes, and he will drift there during the winter.

THE ORE YIELD.—Wood River *Times*: As many of our mining men are beginning to think of going away for the winter, the *Times* renews the request made last year, that it be furnished with accurate statements of the yield of each mine in this section during the past season. Last year the *Times* was put to a great deal of unnecessary trouble by the neglect of a few mine-owners to attend to this matter, and it is to be hoped that the returns will, this year, be more easily obtained. Last year's yield was about $1,250,000; this year's yield must be at least $2,500,000, and the facts and figures which go to make up this total should be published as soon as possible..... F. J. Scott, President of the Guy Mining Co., of Toledo, Ohio, having concluded to suspend ore-shipments until next spring, supplies the *Times* with the following report of the ore-yield of his mine during the season of 1882: Aggregate of shipments, 4½ tons; average value of the same, $142.88; sacked at mine, ready for shipment, 10 tons; total yield, 5½ tons, valued at $7,358 32.

MONTANA.

OLOSTER.—Helena *Independent*, October 12: The last run of the Boston & Montana Co.'s Oloster mine for 13½ days' dropping of 80 stamps, netted $15,344.48, which is the largest gold bar yet made from any single clean up of this company. The vein is nearly 20 feet in width at the point where they are now sinking near the 300 level and is still widening. At the point where the shaft started the walls were 4½ ft apart, about the narrowest place found in the lode. From 100 tons of rock crushed in the Stimple mill, from the Grubstake mine, Milo Courtwright recently brought in 400 ounces of retort, or over $6,000 gold. The ore was taken out in 30 days by 5 miners. A rich strike has just been made on bed mountain, the General Grant, owned by Julius Horst and A. J. Arnold. It was found to be necessary to grade a new road to the shaft of the Nellie Ornat, in order to get the hoisting works in place, and the grading had to be done across the General Grant location. The workmen took off a few inches of earth from the lode and exposed a solid body of most excellent galena, which is found at 8 ft of depth to be 3 ft thick and very pure. Men have been set to work upon the lode and will soon develop a bonanza there or else "bust it out."

NEW MEXICO.

NOTES.—*New Southwest*, October 12: The Telegraph district is booming.....The Avery mine in the Telegraph district is seeking ore to send to Pueblo to be smelted.....A valuable coal lead has been found on the Government reservation about 2 miles from Fort Bayard.....The Tecumseh mine at Telegraph is being actively worked by Bradley, Dorsey & Co., and is producing very rich silver ore.....Mr. Allen has bought an interest in the Cincinnati and the Clara mines, in the Chloride district from J. R. Lacey. Both prospects are now being worked and are looking well..... The Atwood mine, at Shakespeare, is looking very well; they are drifting north and south at the 210 level, and calculate to strike the south vein next week. They are already into the north vein; the company propose to put up concentrating works in a short time..... The Blue Bird mine in Silver creek in the Mogollons belonging to John Lambert, is producing fine gold ore, averaging about $200 to the ton. We were shown a specimen of gold from this mine, $50, that had been obtained from half a ton of ore worked through arrastras..... The Bertha mine in the Mogollons, the property of Messrs. May, Andrews and Tober, is producing large quantities of rich gold ore. The Bismarck, same owners, contains a 10-ft vein of gold ore that averages $120 to the ton; many assays from this property run up as high as $20,000..... The Viola mine, at Pyramid, is looking remarkably well. At the depth of 235 ft they have found a vein of very high-grade ore, containing native brittle and ruby silver and high-grade galena; the assays run up very high; the mill test will probably run up to 150 ounces: this vein is a new strike as their main vein is about 20 ft from the bottom of the working shaft.

ORGANS.—*New Mexican Mining News*, October 12: News comes from the Organs of other rich strikers on Black mountains—the place where the now famous Copper Duke is located. All the ground in the neighborhood has been located, but good properties are being bought from the prospectors at reasonable figures. The Longfellow, Annie Georgian, Ocean Wave and Lufkins changed hands last week. Wm. Dessauer and E. B. Beer, of Las Cruces, obtaining a controlling interest in them. The ores are said to be rich in silver and copper, and free gold is to be found in the Longfellow..... Since the meeting last Friday of the directors of the Sierra companies, the following facts have been learned from the officers: The first dividend on the Sierra Grande will be declared October 15th, and will be at least 25 cents per share. Dividends will be declared monthly thereafter, probably on an increasing scale. The stock will be listed in Philadelphia and New York next month. The Grande mill is turning out $200,000 a month and the mine is out of debt. The general manager reports the running of the drift from the "Bridal Chamber" on the dip of the vein toward the mill for a considerable distance, in rich ore all the way. This development has largely enhanced the value of the mine. Shipments are now being made from the Sierra Bella, and the debt—$45,000 will soon be liquidated and bullion shipped East. Work is to be vigorously pushed on the Sierra Apache.

OREGON.

MINING NOTES.—More prospecting than ever is being done.....Welch & Co. expect to have their quartz mill at Blackwell in running order before long..... Shearer & Co., of Steamboat, are running a long race and expect to strike the channel in due time..... Derickson & Co. have their mill on Horsehead, Josephine county, in operation, and are grinding a fair quality of quartz..... Work is being continued on Bybee & Co.'s ditch near Waldo, with all dispatch, but it will not be finished before the 1st of December..... Bolt & Co. have suspended work on their Steamboat ledge, after running 40 ft of tunnel. The prospects for a ledge of paying quar z are good..... Jack Layton, proprietor of the Farris gulch mine, was in town this week. He has finished cleaning up for this season and took out several thousand dollars..... Philip Mollen, an experienced miner, will build an arastra and begin crushing rock soon at the ledge at the head of Wagner creek, in which he is interested..... J. A. Cook, of Foots creek, was in town this week, from whom we learned that miners are getting ready there for more extensive operations than ever next season..... Berryman & Hauseu, of Applegate, have drifted quite a distance into the bank of that stream and are doing better than ever. Sometimes they get as high as $10 per day..... Speaking of the Klamath river mines, the Yreka *Journal* says that W. McConnell is making about $600 a week clear at his claim, and realizes considerable gold from the surface. He has paid his men about $4,000 the past week..... Beck & Epperson, of Steamboat, have their hydraulic claim in operation and are doing good work. They picked up a nugget worth $10.50 the other day. Coarse gold abounds in that section, a bowlder worth $1,100 having been found there several years ago..... Jas. Lyttle, of Josephine county, was in town last week, from whom we learned that little work is being done in the copper mines near Waldo. The expert who recently came out to look after matters has gone back to Portland with samples of ore, and active operations will not begin until he makes a report..... Dr. Aiken this week showed us a sample of nickel ore that came from the mine a company of California capitalists are developing in Douglas county, of which Wm. Q. Brown is manager. It is said that there are 2,000 tons of it on the dump, some of which will go as high as $200 per ton. Reduction works will probably be put up before long.

UTAH.

FRISCO.—*Southern Utah Times*, October 14: Nearly 50 employes are on the Frisco R. & S. Co.'s pay-roll at the Carbonate mine and concentrator..... The Mascot mines, relative to which the *Southern Utah Times* published some editorial correspondence last spring, has been attached for debt..... During the first six months of 1882 the Horn Silver Co. smelted 25,891 tons of ore, producing $777,377.09 worth of lead, and $952,130 95 silver. The press highly commends the company's good management.

DETROIT DISTRICT.—Another promising location of this district is the Juno, which at about 25 ft in depth shows a solid 2 ft of ore carrying 13 per cent. bismuth, 18 per cent. copper, and 42 ounces silver per ton. The owners of this claim intend shortly to make a shipment to England as a test. The ledge is in a porphyry ledge. Though this is a good district, it is not a so-called "poor man's camp." Water is scarce and has to be packed to wherever work is being done. As I have been unable to answer the question, can any of your readers state whether bismuth ores are worked anywhere in this glorious Republic, or have we got to ship to the "old country?"

ENGLAND'S exports of ingot copper were 18,737 tons, and its total exports of manufactured, partly wrought and unwrought, were 50,126 tons in 1881, against 49,508 tons in 1880 and 49,568 tons in 1879.

A TOTAL of 46,358 tons of fine copper was turned out in England during 1881 by the smelters of that country against 48,907 tons during the preceding year.

The Lead Trade.

We are indebted to the London *Times* for the following valnable article on one of our most important industries: The lead trade was the last of onr important industries to feel the effects of the general commercial depression which set in some few years ago, and it was not unreasonably supposed that a metal of such general application would be the first to improve in value when credit was re-established. For at least half a century the trade has not been in a worse position than in the last three years, in which it is estimated that more than one-third of the lead found in Europe has been sold at an actual loss to the producer. The profits of the smelters have been reduced to a minimum, and even the manufactnrers, who convert the metal into the sheets, pipes, red and white lead, and other articles of commerce, have 'been forced to sell their products at prices which left them little or no return.

Great Britain is recognized as the center of the lead trade and the prices of the London Exchange regulate those of the European markets. The condition of so important an industry is obviously a matter of some interest.

The Relative Quantities of Lead Produced

In different countries may be thus stated: Great Britain, 54,000 tons per annum; Spain, 120,000; Germany, 90,000; Italy, 10,000; Greece, 9,000; France, 15,000; Belgium, 8,000; Austria, 6,000; Russia, 1,500; United States of America, 10,000; Australia and other sonrces of supply, 3,500. Total, 417,000 tons.

The figures are approximate only, and in the case of France and Belgium the sum is principally made up from lead ores imported ont of Spain and Italy.

The United States imposed an import dnty of £9 per ton on pig lead in 1864, since which time the Americ an demand for it from Europe has been practically of no importance.

As far as can be ascertained from our imperfect Board of Trade returns, the lead trade of Great Britain during the last ten years has been as follows:

Year.	British Production, plus Imports.	Exports.	Amount retained or consumed.	Price per Ton.		
	Tons.	Tons.	Tons.	£	s.	d.
1872	148,129	59,904	83,225	20	0	0
1873	127,695	46,479	81,216	23	6	3
1874	133,798	55,531	78,267	22	2	6
1875	148,148	52,058	96,(90	22	10	0
1876	150,624	56,282	94,342	21	13	9
1877	167,783	61,978	105,805	20	11	3
1878	171,708	51,033	120,675	16	16	0
1879	169,087	54,252	114,815	14	16	3
1880	164 963	52,292	112,671	16	7	6
1881	156,500	61,689	94,811	15	0	0

On the recommendation of a Parliamentary Commission in 1871, the items of red and white lead in these returns were included in "painters' colors," which is certainly not a oorrect olssification; shot, used principally for sporting purposes, in "arms, military stores, and ammnnition;" litharge in "chemical manufactures;" and acetate and other forms of lead in "manufactnred articles unennmerated." Under the new headings, therefore, the items relating to lead cannot he ascertained and identified. But probably about 40,000 tons of lead are annually converted here into the manufactured forms above mentioned.

In the table the imports and exports of manufactured lead, the returns of which no longer appear, have been put at 2,200 and 13,200 tons per annnm respectively, those being the amounts returned in 1870.

It is generally believed that the

Production of Lead in Europe

Is in excess of the consumption. There is no evidence in support of such a belief. On the contrary, it is now evident that any overproduction has been absorbed; for stocks—that is, stores of lead ready for sale in this country and abroad—are admitted to be unnsually low. When the fall in the value of lead commenced in 1877, it was supposed that, as soon as the market price fell below the cost price of production, supplies would diminish. The market price did so descend, but supplies, nevertheless, continued to increase, and from the middle of 1878 to the middle of 1880 the heavy production, coupled with the general depression of trade, made lead unsaleable sometimes at £13 per ton. It must, therefore, be admitted that for a time the supplies exceeded the demand. Increased production with low prices, though apparently anomalous, is but a natural result. From an average lead mine, treated with due regard to the capital invested and to its future working, lead cannot be put in the market under £16 10s. per ton. A lower figure would entail direct loss on the producer, unless he exhausts his mine by intrenching upon his reserves, in which case, by neglecting current explorations, repairs, and outlay upon plant, and by increased production, his cost price may be reduced to from £14 to £15 per ton.

When lead fell in valne below £14 per ton, the producer, whose former experience disposed him to look upon such a price as abnormal and as probably of brief duration, had two alternatives. It must he premised that lead mines are, as a rule,

Worked on a System of Royalties;

But a minimum rent is, in most cases, payable, even altbough the mine be nnworked. He might first stop the working of his mine, with the inevitable certainty of future expense in re-opening it, and the risk of its caving in, and dismiss his staff and workmen, many of whom would be practically unfit for other occupations. He would still be under the obligation of paying a dead rent to his lessor, amounting, in some cases, to thousands of pounds per annum, and must absolntely sacrifice all interests on the capital which he had invested; or, secondly, be might economise in every direction, and distribute his expenses over an increased production by attacking the hard-won reserves left unworked from former years. It is not surprising that the latter course was generally adopted, or that relief was sought at the risk of ruining or depreciating the mine. Hence, increased production came to multiply the difficulties of the producer, lengthening the period and the depth of the depression. The inevitable result has been that a large number of mines have been absolntely worked out, which cannot be reopened without the expenditure of much time and capital.

It is contended that, although the depression still continues, the production of lead in 1881 was not the sole or a sufficient source of the supply for consumption. An enormous decrease of makers' stocks in Spain is evident of late years, partly owing to increased railway and shipping facilities abroad, but principally to the necessity of realizing to meet current obligations, which are always onerous on the maker in a falling market. It is plausibly argued that, as manufacturers' stocks in this and other countries have also decreased, the demand for lead has absorbed not only the current supplies, but the additional amount thrown on the market by the reduction of stocks as well.

The Lead Trade of Europe

May be fairly gauged by that of this country. In order to decide whether the low prices of late years, and particularly of last year, are justified, the figures of supply and demand, so far as they are obtainable, may be applied as a test. The supply can be estimated with some degree of precision; the demand can only be judged of by way of inference, and particularly by the rise or fall in the value of lead. The changes of the lead market, when considered for the purpose of comparison, are, perhaps, best observed over quinquennial periods. It is of importance to determine whether the increased rate of production, which is evident, has been accompanied by an equally progressive rate of consumption.

From 1845 to 1849, the earliest period for which fairly reliable returns are obtainable, the total imports into this country, plus native production, averaged 60,377 tons per annum, and the price £17 13s. 9d. per ton. From 1873 to 1877, the period immediately preceding the fall, these figures were increased respectively to 145,609 tons and £22 0s. 9d. Thus the increase in a period of 28 years of 140% on the total quantity produced and imported was accompanied by a rise in value equal to about 25%. It may therefore be assumed that during this period the rate of consumption progressed equally with or in an increased ratio to that of production. The fact is hardly to be wondered at in view of the mere extensive application of lead to manufacturing purposes, building operations, and gas, water and sanitary apparatus.

That a progressive improvement in any particular trade, such as has been clearly indicated above, should receive a check during a time of universal commercial depression, such as was felt in the years 1878 to 1880, is natural enough, especially since the producers, as a consequence of their struggle for existence, caused the amount of "imports and native production" to swell to 171,708 tons, which left no less than 120,675 tons for home consumption. This quantity, however, large as it was, has since disappeared from the market.

In 1881 native production and imports were reduced to 156,500 tons, and the amount for British consumption to 94,811 tons, which cannot be very far from its requirements.

It is admitted that the

Depression of the Lead Trade

Has been largely contributed to by the possession of insufficient capital on the part of a large number of producers, by the absence of banking facilities for obtaining advances on stocks held temporarily at home and abroad, and, finally, by the operations of speculators. Formerly, the entire

Production of Spain

Was exported to other European countries as silver lead. The silver was extracted and the lead rendered marketable by long-established manufacturing firms, having large financial resources and an extensive *clientele*, and well able to remain off the market when there was but a slight demand.

The Spaniards became dissatisfied, not without reason, at the lowness of the prices they received, and commenced to desilverize in Spain. This had a prejudicial effect, and a weak tone was imparted to the market. Whatever the general effect of the policy may have been, it was soon found that in any given district of Spain the smelter who did not desilverize could not compete in buying his raw material from the native miner with another who did, and the lower the prices fell, the more clearly was his position of disadvantage apparent.

With supply and demand in equilibrium, there is a marked difference in the control exercised by strong, as compared with weak, sellers on a margin. The yearly requirements being 150,000 tons, it does not follow by any means that the demand can absorb month by month 12,000, still less weekly supplies of 3,000 tons. If the trade is in strong hands, prices may be maintained over periods of slack demand, while the reverse must take place if the sellers are weak.

Circumstances in 1878, 1879, and perhaps part of 1880, made a fine opening for speculators of which they were not slow to avail themselves. The market was at their mercy during that time, and the hold they acquired upon it enabled them to continue their operations in 1881, when in reality the statistics of supply and demand showed evidence of a state of things which no longer favored them.

The Modus Operandi of the Speculator,

Which has always a tendency to depress prices, is simple, and requires but little working capital, if only to be practiced on a sufficiently extensive scale.

He makes sales or contracts for several months forward for, perhaps, thousands of tons, without being in a position to deliver a tithe of such a quantity (a practice which is not adopted or approved by any *bona fide* lead producer), and he secures the co-operation of the consumers by offering to deliver at a lower price than is ruling at the time. Thus, when the producer enters the market, all the buyers are engaged, and the only purchaser he can deal with is the speculator, who has forestalled him, and who, of course, will only purchase at a lower figure than he has himself engaged to deliver at.

When prices are dangerously low the speculator abstains for a time from operating, and prices improve. He desires, however, '*reculer pour mieux sauter*," and the improved prices, which are allowed to rule during his inactivity, serve afterwards as a new basis for speculative operation.

It is apprehended by pessimists that such an increase of production will follow on improved prices, that a rising market will be choked at the outset. This is by no means likely to follow. There are few lead mines that have not been more or less exhausted by attacking reserves in the quinquennial period, which commenced with the year 1878, and low prices have been shown by experience to have caused an increased outlay. With remunerative prices again prevailing, the first and paramount interest of a mine owner will be to reconstitute the reserves he has been drawing upon, which in a well-conducted mine should represent three years' production. Whatever time he may have occupied in taking out reserves it will require at least four times as long to reconstitute them. A long continuance of high prices will doubtless stimulate new enterprise, but it takes some years to open ont a new mine.

Some Hopeful Signs

Are to be detected. There is, first, the absence of large stocks. The amount in this country of lead actually held back from the market is liberally estimated at 20,000 tons, or £300,000 worth, against which there has been a large reduction of floating stocks in the hands of manufacturers. Copper with stocks of 35,000 tons landed in England, of a value of £2,400,000, has improved £10 per ton in price during the last 12 months. Lead stocks cannot, therefore, be considered high, especially when it is remembered that the trade in it is nearly double that of copper. A second encouraging fact is the absence of any excess of production in 1881. A third is the increasing rate of consumption. Electricity is likely to become the means of creating a new and important demand for lead. The accumulator, storage or secondary battery, is said to be as indispensable an adjunct to electric lighting appliances as a gasometer is to those for generating gas. It is calculated that for each horse lighted by from 20 to 30 electric lamps, about two tons of lead will be required where secondary batteries are used. A demand may, therefore, arise here for thousands and hundreds of thousands of tons. The secondary battery, like electric lighting generally, has not yet emerged from the experimental stage. But already contracts have been entered into for its supply to an extent which absorbs 400 tons of lead per month—an amount not to be despised by the producer, when supply and demand are already supposed to be equilibrium. Another and cheaper medium for what is popularly called "storing" electricity may possibly be found; but, so far as it is at present known, the only metals suitable for the purpose are silver, copper and lead. Long before the demand is so great as to cause the price of the last to be equal to that of either silver or copper, the lead producer may look back with equanimity on the unhappy conditions of the quinquennial period which will terminate in 1882.

In Favor of Coal Mining Machines.

Mr. D. R. Jones, President of the Miners' Union, writes as follows: The colored men are slowly migrating from Rend's mines, Panhandle. The coal mining machines lately introduced into these mines are so far successful. The machines are running night and day. The engineer or person in charge of a machine receives $2 50 a day. The helper, whose duty it is to assist in its moving and to shovel away the bearing in slack, receives $2, and the loaders 40 cents per ton for loading cars, taking down slate and keeping the rooms in shape. Two shifts of men are on working from 6 to 5 in the day time, and from 6 P. M. to 5 A. M. Whether taking it for a year, the mining of our coal with machinery will prove successful, is an interesting question to the miners and the community. If the experiment is a success machines will be introduced sooner or later into all the mines, and the present system of mining revolutionized. This is inevitable. It will avail nothing for the miners to oppose labor-saving machinery in their trade. They are in the line of progress, and they will come, as the locomotive came to displace the old stage, or as the gas took the place of the candle, and as the electric light is now in its turn pushing aside the gas. In this pit with the machines we notice that the men are 11 hours in the mines—about the same number of hours that they worked when there were no machines, and in view of this fact it is pertinent to ask: Of what benefit to the miners would labor-saving be? If they will not insist on a reasonable reduction in the hours of labor with the machines, they cannot possibly be of any benefit, but they will be a decided injury.

To produce the same amount of coal now produced, about one-third less miners would be necessary; the other one-third would therefore be obligated to crowd into the other already crowded trades. We are bound to let the machines come, but we are not bound to work 11 hours per day with them. We cannot stop human mind to invent, nor stop the mechanic from constructing the machine, but we ought to be able to go to the pit, not before 7 o'clock in the morning, nor to remain in there after 3 in the afternoon.

Our prejudice should not be massed against any labor-saving machine, but against long hours with them. Coal-mining machines with long hours would be a curse. The same with shorter hours would be a blessing.—*Coal Trade Journal.*

Forest Trees of California.*

Pacific Silver Spruce.

(*Tsuga Pattoniana* [*Abies Williamsonii*].)

"Far off, indistinct, as of wave or wind in the forest."—*L.*

The silver spruce,† as its common name *par excellence* suggests, is by far the most cheerily silvery of all the conifers of the Pacific. The early growth of this species, as seen in the high Sierras, say from 7,500 ft. to 10,000 ft. altitude in California, or 6,000 ft. in Oregon, is elegantly spiry, branching broadest from the base, often in a decumbently ascending direction, at length outwardly pending tips, and so tapering aloft to the plumy top. The crowded wealth of fasiculoid foliage, waves and surges the spray with such wonderful variety, that its outline reflects the silvery lights and shadows to the greatest possible advantage. The weight of wintry snows often gracefully curve the base adown the steeps where they cling, thence righting up their recoil, the top compensates by an opposite curve, thus gracing this impress of an early life-struggle for existence by another charm—a crowning wreath on the brow of victory.

The middle-sized cones are perfectly symmetrical and smooth, subelliptically cylindroid, from two to three inches long, about three-quarters of an inch broad, purple and softly bloom-tinted. They tip singly or in clusters, the slender twigs, thus bowing to their weighty burden, they strike you as exquisitely ornamental. These slender branchlets are pubescent, leaves from one-half to an inch long, convex or keeled, *i. e.*, angled above, rather sharp pointed, narrowed at base and curved, stomata on both sides; male flowers about two lines long on sleuder thready stems; pollen grains bilobed, blooming in September and October; seeds two and one-half lines long, wing about one-quarter of an inch or less than twice the seed, obliquely obovate and widest above. Many of these trees in the closer forests are tall and slender, from 75 ft. to 100 ft. or more in hight, often irregularly branched, but they are always graceful and never formal. On open borders, with greater freedom for development, they are both grand and graceful—the finest of all the spruces. The sturdy, elegant trunk, of rather even reddish brown hark, reminds one of the sugar pine. Column often clean from 50 ft. to 100 ft., and 6 to 8 ft. or more in diameter, thence above branching into a broadened conic top, duly balanced to lines of beauty up to 150 ft. or even 200 ft. The best types we have witnessed are at the summit of the Sierra Nevada mountains, which certainly seemed, to our enchanted view, as though they must be, for their style of beauty, equal to any spruce in the known world.

The special form and analytic illustrative figures in Vol. VI of the U. S. R. R. reports, are our own paintings. That portion, however, showing the reflexed condition of the scales, is superadded to the original drawing, and is not characteristic. This condition of the old cone scales of the cone exposed to a burning sun, is also common to other conifere, and is eminently conspicuous in the cones of the Western Mountain Weymouth pine (*P. monticola*), etc.—we simply note the fact in passing. Typically, this tree is pyramidal, 100 ft. to 150 ft. high, and from 2 to 4 ft. through; but in high altitudes of California, say 8,000 to 10,000 ft., is often only a shrub. In the north latitude of the Cascades to near Crescent city, it comes down almost to the coast in due form.

* From "The Forest Trees of California," by A. Kellogg; published by the State Mining Bureau. State Printing Office, Sacramento, 1882.

† The name "spruce," as contradistinguished from "fir," in common parlance, implies that the cones pend gracefully down from the tips of the twigs, and are distributed over all parts of the tree, instead of the top only, and that the scales and their appendages persistently hold together and fall off at once, when ripe, like many pine cones; also, that when the flat two-sided and two-rowed leaves fall off they leave the sharp woody-like base or foot stalk prominent, and no spirally arranged bark-scars as in firs and pines; and as the cones do not stand upright like birds upon the upper boughs near the top, and fall to pieces at maturity, of course they leave no naked, spindle-shaped, woody axis still perched on the place where they grew as the firs do, and the bark never blisters as in spruces. In thus defining these common names, as they are and should be used by us, only a few strong points of contrast can be wisely noted; others more technical are intentionally omitted.

What Steam Does.

It was estimated a number of years ago—1875—that the services rendered England alone, by the great agent of steam, was equal to the combined muscular effort of 100,000,000 of men. In our country, the service and utility of this agency can only be approximated as millions of times greater than one man's strength. The full force of these statements does not appear at once. It remains for the silent investigator and student to solve the problem of what this means. That we may place the question at once before us, let us suppose that steam and its appliances were to be taken away from us. Would we be as well situated as we are to-day, even though in England alone there would be employment for 100,000,000 more men? The well-informed person will answer at once, no. Steam has made a revolution in the world's industries and man's occupations almost beyond computation. Before its discovery, men were content to live year after year scantily tilling the soil, and making such crude implements as his daily wants suggested. To carry on our industries of the present day—manufacturing, commercial and mercantile—there has been taken from the agricultural classes, almost the number of men employed in these different avenues of labor. This could never have been without the interposition of such agencies as steam, and the various labor-saving appliances. And by these means man has been able to accumulate wealth faster, improve his condition and better his surroundings. By these means we have come up from an agricultural and rural people, to the greatest manufacturing country of the globe, England possibly excepted. As a people, we can do much more than our fathers could. The division of labor which has resulted from the great activities in all branches of industry, has made our hands more cunning and capable. If we want a chair, we no longer go to the forest, fell a tree, transport the timber to our workshop, form the parts and put them together in a chair by our own labor. Chairs are no longer made in this manner. A chair made thus would be, at best, but a rude and imperfect article, and would cost, at least, the labor of two days.

By a division of labor, we find one man cutting the timber, another taking it to the mill, a fourth sawing it into suitable dimensions, still another forming the legs, another the seat, another the back, another puts the parts together, and finally another paints it. A great many chains are thus produced by the combined labor of the many, and the result is, that each chain represents only the value of half a day's labor. Thus we have a saving in the one transaction of a day and a half, and the article produced is much finer, and better in every particular—so in all branches of manufacture and industry. Our shops are thus enabled to turn out hundreds of machines daily, whereas, a few men, or even the same number of men, attempting to make complete machines by their own labors, accomplish results far less in value. And now, some of our readers may begin to wonder what all this has to do with the application of steam and other agencies controlled by man, in industries. This it is. Steam gave us the means of building up manufacturing. It drew men's attention from agriculture to a great extent and commenced the long line of inventions which we see daily, becoming larger. It has introduced industries and labors previously unknown and not cherished. It has attracted men to these, and now the laboring men of this country earn their bread and support themselves and families less by agriculture and more by the industries that steam and its appliances and products have given us.

It probably does not need proof that the great advances made in manufacturing, whereby man has been supplied with labor saving machines, until one man can almost do the work of ten, are not only to the advantage of the capitalist but also of the laborer. Thus new avenues of labor are daily opening up, and will still continue to. The application of steam is the starting point from which this great advance has taken its rise.

To Prevent the Skin from Discoloring After a Blow or Fall.—Take a little dry starch or arrowroot, and merely moisten it with cold water, and lay it on the injured part. This must be done immediately, so as to prevent the action of the air upon the skin. However, it may be applied some hours afterwards with effect. I learned this when resident in France. It may already be known here, but have met with none among my own acquaintances, who seem to have heard of it. Raw meat is not always at hand, and some children have an insurmountable repugnance to let it be applied. I always make use of the above when my children meet with an accident, and find that it keeps down swelling, and cleanses and facilitates the healing of scratches, when they happen to fall on the gravel in the garden.

The Telephone Under Water.—When the vessel, *La Provence*, which sank in the Bosphorus, was being raised, the telephone was added to the diver's equipment. One of the glasses of the helmet was replaced by a copper plate, in which a telephone was inserted, so that the diver had only to turn his head slightly in order to receive his instructions and report what he had seen. The adoption of this means of communication in diving operations will, in case of danger or accident, tend to insure safety to lives that otherwise would have been sacrificed,

Useful Information.

Blue Fire as an Explosive.

Quite a number of serious explosions have occurred of late under very mysterious circumstances. The explosions have led to careful scientific investigations, which have culminated in the discovery that the preparation known as "blue fire," and which is so much used in pyrotechnics, tableaux, etc., is, under certain circumstances, one of the most violent explosives known. Prof. Samuel Jackson, who owned a pyrotechnic establishment in Philadelphia, and who recently suffered a severe pecuniary loss from such an explosion, the violence of which could not be accounted for by the quantity of explosive material in his establishment, has been foremost in the investigations alluded to. He obtained his hint from an explosion in New Zealand, which resulted from throwing a little water on some blue fire while in the process of burning.

The Professor had made blue light for nearly 40 years, and had never known it to develop extraordinary force; yet, acting on the hint given by the New Zealand accident, he set about making experiments, which have convinced him that blue-light powder, fired by a detonating compound, is not only explosive, but more powerful than dynamite in its explosive effects. In a public experiment to test the explosiveness of blue fire, made at Woodbury, N. J., a tube containing a couple of pounds of the blue fire was placed in the earth and a huge stone laid on top of it. The party went off a couple of hundred feet, and the detonation was caused by electricity being applied to a percussion cap. The effect was startling. The stone was shattered into fragments, a large hole was dug into the ground, and a cloud of dirt and dust thrown into the air at least a hundred feet. The same amount of powder was exploded under exactly similar conditions, but the result was nothing worth speaking of. A little gunpowder was placed in the top of the can of blue fire, and it was exploded with about the same result as the previous one had been. Fire was applied to a can of the blue fire, and it merely burned up.

Speaking of this and subsequent experiments, Professor Jackson said to the Philadelphia *Record* that concussion will always cause a detonation of blue fire, especially when it is highly heated. He believes that the explosion in his factory resulted from a spattering of water on the highly-heated packages containing the blue fire mentioned. A direct stream of water, he thinks, could not possibly have resulted in an explosion.

Professor Jackson believes that blue fire will be found valuable as an explosive for blasting purposes. It is more powerful than dynamite, and safer, since it is a more staple compound, and is not liable to explode when struck with a hammer or when dropped. By means of a percussion cap, or the concussion of exploding gunpowder, it explodes readily, wet or dry.

There are two kinds of blue fire made. One is composed of chlorate of potash, three parts by weight; sulphur, one part, and ammonio-sulphate of copper, one part. Another and safer kind is made without sulphur. Its formula is: Ammonio-sulphate of copper, eight parts; chlorate of potash, six parts, and shellac one part. The salts should be dried on a plate or shovel, powdered separately, and then carefully mixed with a spatula on a sheet of paper.

Polishing Woodwork.—Soft woods may be turned so smooth as to require no other polish than that which can be given by holding fine shavings of the same wood against them in the lathe. For polishing mahogany, walnut and some other woods, the following formula is given: Dissolve beeswax by heat in spirits of turpentine until the mixture becomes viscid. Apply with a clean cloth, and rub thoroughly with another flannel or cloth. Beeswax is sometimes alone used. For work in position, it must be melted and applied and rubbed as above. For work in the lathe, it can be applied by friction, the slight amount of wax melted being sufficient for the polish. The work should be thoroughly rubbed. Mahogany may be polished by rubbing first with linseed oil, and then by a cloth dipped in a very fine brick dust. Some hard woods have a natural polish, and do not require a polishing medium. A fine gloss can be produced by rubbing with linseed oil, and then holding shavings or turnings of the same material against the work in the lathe. A very perfect surface can be obtained with glass-paper, which, if followed by hard rubbing, will give a beautiful luster. Luster can also be given to carefully finished surfaces by applying a small quantity of thinned varnish, shellac or "fillers," by a cloth, and carefully and thoroughly rubbing.—*Comstock's "Interior and Exterior Details."*

Spirits of turpentine are now made from sawdust and refuse of the sawmill. It is extracted by a sweating process, and yields 14 gallons of spirits, 3 to 4 gallons of resin, and a quantity of tar per cord. The spirits produced have a different odor from that produced by distillation.

Cotton seed oil is now coming into use as an illuminator, said to be superior to lard oil, making a pure, white light and emitting no smoke. As far as the test has gone, it is especially useful for mining purposes, as it will not congeal as quickly as the lard oil.

A Curious Case of Demolition.—The *Building News* relates a singular misfortune which has occurred to a small church in Andover, Mass., which seems to be in process of being eaten up bodily and swept away. The church was erected about six years ago, and is finished with what is said to be ash, but has more the appearance of chestnut, which often closely resembles the coarser kinds of ash. A year or two after its completion the sexton noticed little heaps of dust on the carpet near the walls. These grew more and more frequent, and appeared in various portions of the building, so that they had to be gathered up regularly every week, and on searching for their cause the wood of the base-boards and portions of the pews was found to be completely riddled with holes made by small, round, black or blue worms, the *debris* of whose boring fell out occasionally upon the floor in the form of dust. Unlike most boring worms, this species seems not to object to the taste of varnish, for the polished surface of the wood is pierced in thousands of places. The stock was regarded as completely seasoned and in good condition when put into the building, but it would seem that it must have contained the embryos of the insects, for the finish of the galleries is attacked equally with that of the ground floor. If any of our readers, adds the *News*, meet with a similar case we should be pleased to receive an account of it, and if any know of a remedy, the trustees of the church would be glad to avail themselves of it.

A Peculiar Industry.—A peculiar industry is that of making clog soles and wooden shoes. The timber is first cut into planks, and on the side of each plank a metal gauge is laid, an operative then roughly outlining the size and number of soles which can be cut from it. The planks pass on to a hand saw, where they are cut up into blocks with the required curvature for a sole, thence passing to the roughening machine which crudely shapes them. Another machine cuts the sides, another shapes the shanks, a third rounds the heels, and the toes are shaped by a fourth. From these they go to a revolving cutter, which roughly hollows the upper side of the sole, and subsequently this hollowed surface is smoothed in another machine. The soles pass next through various finishing machines, the bottoms, sides, shanks, heels and toes being thus successively rendered perfectly smooth by friction with swiftly revolving hands—the latter covered with a mixture containing ground glass and some other attritive materials—which scour them in the same way as if with sand or emery paper. Finally a gripping machine bevils the edges, leaving a "grip" to which the leather uppers can be fastened. The sole of each wooden shoe, from the time when the log of wood is first cut into segments to the time when the edges are beveled by the gripping machine, passes through 15 distinct machines.

Good Health.

Patent Medicines.

All patent medicines are not good, nor are all of them bad. Some of them are composed of excellent materials, and are very valuable; a few, comparatively, are either really useless or dangerous. Far the most part of these compounds are based substantially on well-known formulas, the chief distinguishing feature being in coloring or flavoring. The money value of any one of these preparations represents the business skill of advertising and pushing.

For our part, we fail to see why the "Sarsaparilla," or "German Syrup," or "Catholicon," or other line of trade is not just as dignified and advantageous to the public at large as the manufacture of soda fountains, or lager beer or any of the many branches of employment that gratify men's tastes, or their whims or notions.

The following figures will show the numbers of the several kinds of these mixtures or compounds:

There are fully 2,000 different corn cures sold by dealers. The number of balms for the lungs, rheumatism, consumption, etc., is 46; balsams, 96; stomach bitters, 106; cordials, 48, catarrh, asthma, skin, cough, rheumatic, heart, cholera, dyspepsia, ague and other cures, 137; drops, 48; elixirs, 77; extracts, 131; hair dyes, 23; hair tonics, 16; liniments, 151; lotions, 34; lozenges, 57; hair oils and cod liver oil preparations, 150; ointments, 87; pills, 312; plasters, 157; powders, 163; various remedies, 142; different kind of hair restorers, 68; salts, 29; salves, 75; snuffs, 18; soaps, 129; specifics, 66; syrups, 188; tablets, 27; tonics, 51; troches, 32, and medicinal waters, 75. Besides these articles there are many others with extraordinary names, and to be a good salesman in such an establishment, it is necessary to remember all of the 5,000 different articles in the place.

Biting the Nails.—It is a bad habit for one to get into, for the reason that those who become addicted to it forget themselves, wherever they may be, and when embarrassed they are especially apt to indulge it. The injury which is done in most cases to the fingers is one of deformity—who likes to see the stubby, uncouth finger-ends which inveterate nail-chewers show? We have the impression that the practice has a mischievous effect on a person's mouth, distorting its shape, perhaps thickening the lips, possibly giving an abnormal tendency of growth to the jaws and teeth.

Celery as a Cure.

The habitual daily use of this vegetable is much more beneficial to man than most people are aware of. A writer who is familiar with its virtues says: "I have known many man and woman who, from various causes, had become so much affected by nervousness that when they stretched out their hands they shook like aspen leaves on a windy day, and by a moderate daily use of the blanched footstalks of celery as a salad they became as strong and steady in limb as other people. I have known others so nervous that the least annoyance put them in a state of agitation, and they were in constant perplexity and fear, who were also effectually cured by a moderate use of blanched celery as a salad at meal time. I have known others to be cured of palpitation of the heart. Everybody engaged in labor weakening to the nerves should use celery daily in the season and onions in its stead when not in season."

To this we may add that a prominent New York druggist draws in winter from his soda fountain a hot extract of celery, mixed with Liebig's meat extract, under the name of ox-celery. It is a nourishing drink at lunch time, far better than coffee or tea, and is doing a great deal in this neighborhood to promote temperance. We give celery almost daily to our canary birds, and it cures them of fits; they are little animals with very delicate nerves, easily frightened, and therefore they need such a remedy very much, and the relish with which they take it is a proof that their instinct guides them to eat what is good for them. A manufacturer of perfumery of our acquaintance, some years ago, commenced to prepare an extract of celery seed, put up in bottles, and intended to give strength to old or exhausted persons who, by over-indulgences, have reached such a state as to require restoratives.—*Journal of Chemistry.*

Relation of Brain Work to Blood Supply.—Even if it is true that the larger and healthier physique affords more blood for brain use, it does not follow that the larger the supply the greater the amount of brain work possible. The argument assumes that the brain has no limit to its activity, except in the quantity of blood that can be prepared for it. But it needs no scientific education to know that there are other influences which limit the thinker's activity, and that these limitations are somewhere in the mysterious recesses of the brain, or in the forces of which the brain is the organ. The physical health of the brain worker may be perfect, his digestion unimpaired, his power to assimilate food the same, and yet he may not be able to concentrate his thoughts or carry on a complicated train of reasoning. The defect is not in his body; that is as healthy as ever; nor is it in any of the processes of blood making—these go on as before. The trouble lies in the brain itself, whose capacity for work is measured by some hidden standard of its own, and which gives warning when a cessation of brain work is imperative. The body is a furnace whose power of consuming fuel is greater than the capability of its boiler, the brain, to generate power. To keep the latter in good working condition, something more is necessary than building and feeding the fires. A supplementary but important consideration is, whether the steam beyond a certain point will not be productive of unpleasant consequences in the form of an explosion.—*Popular Science Monthly.*

Frightening Children.—Nothing can be worse for a child than to be frightened. The effect of the scare is slow to recover from; it remains (sometimes) until maturity, as is shown by many instances of morbid sensitiveness and excessive nervousness. Not unfrequently fear is employed as a means of discipline. Children are controlled by being made to believe that something terrible will happen to them and punished by being shut up in dark rooms, or by being put in places they stand in dread of. No one without vivid memory of his own childhood, can comprehend how entirely cruel such things are. We have often heard grown persons tell of the suffering they have endured, as children, under like circumstances, and recount the irreparable injury which they are sure they then received. No parent, no nurse, capable of alarming the young, is fitted for her position. Children, as nearly as possible, should be trained not to know the sense of fear, which, above everything else, is to be feared in their education, early and late.

Sunshine and Sleep.—Sleepless people—and they are many in America—should court the sun. The very worst soporific is laudanum, and the very best, sunshine. Therefore, it is very plain that poor sleepers should pass as many hours as possible in the sunshine, and as few as possible in the shade. Many women are martyrs, and yet they do not know it. They shut the sunshine out of their houses and their hearts, they wear veils, they carry parasols, they do all possible to keep off the sunlight and yet most potent influence which is intended to give them strength and beauty and cheerfulness. Is it not time to change this, and so get color and rose in our pale cheeks, strength in our weak backs, and courage in our timid souls? The women of America are pale and delicate; they may be blooming and strong, and the sunlight will be a potent influence in this transformation.—*Rural New Yorker.*

Passing Events.

Just about this time those superintendents who have any forethought are getting in their winter supplies. In the more mountainous regions, where most of the mines are situated, the roads become more or less bad in winter, and oftentimes serious inconvenience is felt for some articles which might as well have been supplied long before, while the weather and roads were good. In the matter of fuel particularly it is well to have an abundant supply on hand, ready for any emergencies. In looking over our exchanges this week we see that at many mines preparations for winter are being energetically carried out.

News from the mining regions generally is pretty good, as a perusal of our mining summary will show, but we have no startling strikes to note. Prospectors are just now hunting winter quarters, or going to the south, where they can get in more or less days work during some of the winter months.

THE Carson river is rising, and numerous searchers for gravel deposits and tailings have been obliged to abandon their pursuits. In many places along the banks the small handwheels used for drawing pits can be seen, the crank and portions of the belt still above the water, while an occasional broken shovel or abandoned screen also show where the search for auriferous and argentiferous floatsam was prosecuted during the low stage of water.

WM. MAXWELL, of Virginia, Nev., and for a long time foreman of the old Eleshardt mine, has been appointed foreman of the Eureka Tunnel.

Mines and Progress.

There are in the Eastern States, and even among us here, many who will speak of mining as an interest inimical to the welfare of a people, owing to its fluctuating and hazardous character, and to the contempt it is supposed to get for the more gradual methods of acquiring wealth. There is some truth in this view when it is confined to the early style of mining, which despised restraint and debauched the morals, as it impaired the constitutions of those who followed it in the spirit of wild adventure. But the objections do not lie against mining as a regular systematic pursuit, directed by skill and capital, and relying upon the steady continuance of moderate profits. This kind of mining the past 10 years has shown to be one of the most permanent and healthful sources of prosperity. The applications of American ingenuity and enterprise to the developments of the deposits of the precious metals found west of the Rocky mountains has made gold and silver mining as legitimate and safe a business as mining for coal or iron, and as great a promotion of diversified industry.

Experience has made us all admit that with all its evil effects upon individuals, even its old systems have carried most important general benefits, especially in anticipating by generations the peopling the unmerous countries of the West, and thus widening the field for the display of national energies, broadening the spirit and bracing the national credit. But for the mining furore in the earlier days of California the State would have remained a cattle range to this day.

All the great States and Territories that adjoin it, now peopled with civilized communities would still be savage ranges held and controlled by barbarians, now retiring so fast before the forces of modern progress.

Instead of this, immense areas have been prospected, opened up and developed, settlements have been made, cities built, manufactories established, railroads built, and vast tracts of uninhabited country brought into use. Unless the pioneer prospectors and miners had gone into these regions they would have been desolate to-day. If the search for mines had not been made the agricultural possibilities would not have been known, and where there are now farms and gardens, the cactus would have held possession of the soil.

The Indians have been displaced by civilized beings, and railroads have broken the solitudes with their progressive features. Hundreds of mines are being worked, giving employment to thousands of men, and producing their millions of dollars. All these can be traced directly to the influence of the mining interests. It is time, therefore, that mining, as a branch of legitimate industry, should receive full recognition, and those who cavil at it should be told to consider before they speak.

Gypsum.

We have received from Arizona a specimen of gypsum in a thin sheet that led its finder to suppose he was sending a piece of isinglass. Our correspondent states that there is plenty of the substance, some of the sheets being 20 inches square. It is really gypsum, and is not of a variety that has any commercial value in this market. The dealers will not buy it, saying it does not make a good plaster. Where this is found, if the prospector will look and see if he can find the amorphous kind, he may get something of value.

The translucent crystalline varieties are known as selenite (from "selene," the moon in allusion to the characteristic soft luster); the finer, granular, sub-translucent, massive kinds, as alabaster, and fibrous varieties as satin spar. Heated, the mineral gives off its contained water, and becoming opaque, falls to a powder, which has the power it moistened, of rapidly setting or assuming again the solid form. Upon this property depends the most extensive application of the mineral in the arts, as plaster of paris is made from it by heating and subsequently heating it into a fine powder. It is also used as a fertilizer, and in the manufacture of glass and porcelain. Alabaster being of greater beauty and easily carved on account of its softness, is extensively used for ornamental purposes.

That variety known as amorphous is the best. It looks like a stearine candle or alabaster.

This and the variety that looks like marble is the kind that will sell. That which comes in sheets like the specimen we refer to will be useful in Arizona some day for a fertilizer, but at present it is of no use.

It is as well for miners to be reminded that the law does not recognize gypsum as a mineral within the meaning of the Mining Act. On the question being once put to him, the Commissioner of the General Land office decided that lands of the public domain, containing deposits of gypsum, which is of similar formation to limestone, are not subject to disposal under the mining act. It was thought that as limestone underlies a great portion of the territory west of the Missouri river, to reserve such lands as mineral would entirely prevent its development for agricultural purposes.

A TELEGRAPH cable is to be laid under Lake Superior next summer.

The Denver Exposition—No. 10.

[Editorial Correspondence.]

SAGUACHE COUNTY.

Saguache county is situated on the eastern slope of the divide, and between that and the Sangre de Cristo—Blood of Christ—range of mountains. It is reached by the main line of the Rio Grande railway, which runs from Denver south to Pueblo, and thence to Leadville. To go to Saguache you take the road to Pueblo, leave it at Salida, and take the San Luis Valley branch. This road takes you to the Poncha pass of the Sangre de Cristo, from the summit of which the traveler may obtain a splendid panoramic view of the great San Luis valley, which is spread out before him, reaching away off, in the dim distance to the south into the Territory of New Mexico. The most of the county lies within the northern portion of this valley, and forms as valuable a section of farming land as can be found in the State. This valley is already improved to a considerable extent for general agricultural and grazing purposes. Its fitness for agricultural purposes was known to the early Spaniards, who first found their way thither early in the present century. A romantic story is told of a wealthy Spaniard who lived in this valley in 1810—how he lost his wife, and soon after his son was killed and three lovely daughters kidnapped by Indians. The attempt to rescue them resulted in the death of the entire party, including the Indian kidnappers themselves. Many other legends of a similar character are told of the early history of this valley, and many are the bloody duels which have been fought between whites, and sometimes between the white and red man, beneath the lofty shadows of the Sangre de Cristo. By reason of these bloody records the valley is sometimes called the "Vale of Tears," but at the same time it is generally considered the loveliest valley in Colorado.

But the inevitable law that barbarism must yield to civilization rules here as elsewhere, and the haughty aborigines that were once the lords of this valley are now no more, or, at best, are only represented by a few wandering tribes, broken down in spirit and person. They have gone to the "happy hunting grounds," and busy husbandry now rules in the valley, while the echo of the white men's axe and pick is heard everywhere through the surrounding mountains. While we drop a tear over the sad fate of the dusky warriors who have gone, and of whom nothing remains but their memory, we can but "bless the stout arm and stouter hearts of those daring pioneers who braved the dangers of the wilderness" and made possible the presence of a civilized race, before whom this valley is already beginning to bloom with new and far more beautiful verdure than it has heretofore worn.

The Mines of this Region

Are just beginning to be developed. Although the out-put of 1881 was only $53,500, the promise for the future is most encouraging. The county made a very fine exhibit at the Exposition, under charge of L. P. Philips.

The mining districts of Saguache are Kerber creek, Ford creek and Blake. The principal camps in Kerber district are Sedgwick, Bonanza, Exchequer and Dexter; in Ford district the only one is Bonita; in Blake district are Oriental, Crestone and Cottonwood.

About Kerber Creek district the ores are argentiferous, their chief features being galena and grey copper, and they run from $50 to $20,000 per ton.

In Blake district, at Oriental, smelting ores preponderate, while at Crestone and Cottonwood they are free milling, and run from $50 to $5,000.

In Ford district the ores are auriferous and argentiferous, and in some instances free milling.

In the Kerber some of the principal mines are the Empress Josephine, the ores of which thus far have proven very rich, sometimes running up to $250 per ton and over; the Rowley ore reaches an average of fully $35, besides a strata of concentrated lead ore worth $55 per ton; the Exchequer is a very heavy vein of gray copper and carbonates, the average yield of which, it is claimed, reaches $250 per ton.

In the Blake district is the North Andover mine, in granite formation, containing a solid strata of lead ore 2 ft. wide, running $63 per ton.

In the Ford Creek district lies the Last Resort lode, an immense vein. The ore runs from $100 to $1,000 per ton. The ore is mixed and carries some brittle silver.

We now pass over the Rocky Mountain divide into another very remarkable region which is just now attracting much attention. This region embraces a number of counties, which are generally classed together and known as the

THE SAN JUAN COUNTRY.

In the extreme southwestern portion of the State of Colorado there is a region of country comprising five or six counties which, until quite recently, has been a kind of *terra incognita*, on account of its distance from any commercial center, and also by reason of the almost inaccessible nature of the approaches by which it may be reached. Fremont and other early explorers of this part of the continent passed wonderingly around its boarders, admiring the vastness of its mountain solitudes, but never venturing to scale its rugged heights or explore the recesses of its dark and shaded valleys. It was left for later years, and for the more venturesome and persistent gold seeker to accomplish this work, and to unlock, for the benefit of mankind, one of the richest strongholds of the precious metal, which nature, in her secret workings, has stored up and kept intact, until a race of men appeared which could appreciate and fully utilize the vast treasure which has been prepared and reserved to crown with more than regal honors, the wonderful progress which the world has made during the last 50 years.

Work of the Prospector.

In the process of time the venturesome prospector, far in advance of the moving column, which had taken possession of the central portions of the State, pushed on in his travel until he came in sight of this wonderful region. Its difficulties had no terrors for him. Unlike the great "Pathfinder," who sought for the easiest and the lowest pass from point to point, the prospecting miner disdained the grassy plain and valley, and struck boldly out for the ridge and mountain top. Here was a work and a venture suited to his mettle. He climbed, he saw, he conquered. Bye and bye faint reports from returned prospectors were noised abroad in the settlements and mining camps of wonderfully beautiful valleys, of towering snowclad mountains and of fabulously rich and true fissure veins of silver and gold and copper. Mountains of coal, immense beds of the finest iron ore, and plentiful deposits of lime were also reported, waiting only for the skillful hand to marry them for the benefit of mankind. Adventurous men were now found in great numbers to push out into these distant solitudes, and soon the noise of the axe, the hammer and the pick were heard there, and the loud reverberations of giant powder woke the echoes of the mountains. The silver and the gold were found in abundance, but too closely locked in their gangue to yield to ready manipulation, and "the place where they find it" was distant, and the road thither was rough, and vast stretches of waterless and verdureless plains intervened between the miner and his supplies. Discouragement was ill concealed; men became restless and nervous and tired of waiting. Examinations and tests and prospects innumerable proved most conclusively that the precious metals were there in abundance, and only the proper means were needed to make them available. By-and-by the cry went up

"Let us have a Railroad"

But who was to build it, or where was the engineer bold enough to propose such a work? Still, *nil desperandum* was the motto, and men were soon found equal to the task. The positive richness of the mines was proven and made known, and with an intelligent apprehension of the wonderful possibilities of this new mining field, the experts of the Denver & Rio Grande railroad pronounced the work feasible, and the managers gave the word to "go ahead." Skilful engineers were promptly sent into the field; but a direct route to Denver was found utterly impracticable, and Pueblo was made the starting point. Neither the sterile plains from that point, nor the awful hights of the Veta Pass, nor the staggering difficulties of Toltec, nor even the terrible natural obstructions heaped up between Durango and Silverton possessed terrors sufficient to turn back these determined men. They have gone steadily onward, surmounting one difficulty after another, until all was accomplished, and the railroad is now a fixed fact—built not for a day nor a year, but with a solidity and time-defying massiveness that will bid defiance to the elements for centuries to come. A short distance above Durango the road ascends at the rate of 132 ft. to the mile, and keeps that grade for about 30 miles. At La Veta Pass it ascends at a grade of 217 ft. for several miles. The completion of this road formed

A New Epoch

For the San Juan mines, of which Silverton is the very core and center. It at once infused new life into the breasts of the hearty miners; and the old enthusiasm which first set them on foot was renewed, and a new set of prospectors pushed out to the more remote parts of these mountains to open up still new mines from which the precious treasure is already beginning to make its appearance. The miners of San Juan have reason to and do bless the railroad and its enterprising and efficient management. The first screech of the locomotive was heard in Silverton on the Fourth of July last.

The Value of the Mines.

As proof of the great value and prospective permanency of these mines, we have the evidence of J. Alden Smith, the State Geologist, who, in his official report for 1881, writes as follows: "The almost unlimited mineral resources of this (the San Juan) region are undeniable, and its former isolated situation, lack of transportation facilities and reduction works are the sole reason why it has not long since become one of the great bullion producers of the country. It has many very large veins of low-grade ore, which can only be made profitably productive by the aid of railway transportation and extensive concentration works," which they now have. It moreover appears that enterprising capitalists who understand and appreciate the situation and the profits to be made in the near future are rapidly obviating this difficulty by erecting extensive reduction works.

Mr. Smith, in his report, further on says: "The veins of the San Juan region are principally true fissures in the archæan rocks, with many contact veins between that and the volcanic rocks with which most of the region is covered. The devonian, silurian, carboniferous

and cretaceous are also quite extensively represented at different points."

Still Further Testimony.

Prof. Thos. B. Comstock, a gentleman of the highest scientific attainments, and of widely known and universally accepted probity, who has been for years on the ground in charge of various scientific and industrial enterprises, speaks very highly of the present and future prosperity of mines of this district. Although freights have been reduced somewhat since the road was first opened, it was thought that if a still further reduction should be made, to a figure which would yet leave a fair margin of profit for the road, a large class of low-grade ores, which are now neglected, would add their tonnage to the road and greatly increase the output of bullion. W. B. EWER.

Foundry Notes.

The Pacific Iron Works are unusually busy just now with mining machinery of different kinds. Among other work now in process is a 20-stamp dry-crushing mill for a prominent mine in New Mexico; a 5-stamp mill for Lower California, and boisting works for the Christy mine at Picche. They are also building for the Benicia Flouring Mills one of their Wheelock automatic cut-off engines, with boilers and surface condensors, of 350 horse power. Also an engine of the same make and size for the new flour mill of J. M. Welch & Co., at Stockton, and a number of smaller engines.

In the construction of water jacket furnaces, which is a specialty of this establishment, and which we have before described, a very large number of orders has recently been received by Messrs. Renkin & Brayton, among which are the following: A 30 ton combination stamp and smelting plant for the Massachusetts and New Mexico Con. Mining Company; a 30-ton Galena smelter for the Miners' Smelting Works at Galena, Colorado, and a 30 ton plant, complete, for shipment to Australia. Besides those above mentioned, a large number of orders of less importance are being filled at this foundry.

This establishment has shipped within the past few weeks no less than 11 complete furnace plants, of an aggregate daily capacity of about 400 tons of ore. This shows the extent to which ores melting is being carried on on this coast. These water jacket furnaces are well liked wherever used. For lead and copper they have no superiors. The works have been running night and day for some time past. Mr. Brayton of the firm is now in the Eastern States, and will establish agencies in Chicago, New York and elsewhere.

Ten new pumps are being made at the Fulton Foundry, which will be put in position in six weeks or two months at the Union shaft on the Comstock. The pumps are 17 inches in diameter. Thus the pumps will have greater power and capacity than the old ones. The old column, which is 14 inches in diameter, will be retained, as all the water that will be raised can be sent up through this column. It will take about three weeks to make this change of pumps. Meantime the water will be handled by the tanks and by the Ophir and C. and C. pumps. There will be put in a new pump rod for a distance of 1,000 ft. down the shaft. This rod—the 1,000 feet—will be 18 inches square, while that below will remain as at present. The large size of the rod in the upper part will stiffen and steady in the thrust.

THE LAKE VALLEY MINES.—The New York *Tribune* contains the following semi-official statements in regard to the Lake Valley (N. M.) mines: "Since the meeting last Friday of the directors of the Sierra companies, the following facts have been learned from the officers: The first dividend on the Sierra Grande will be declared October 15th, and will be, at least, 25 cents per share. Dividends will be declared monthly thereafter, probably on an increasing scale. The stock will be listed in Philadelphia and New York next month. The Grande mill is turning out $200,000 per month, and the mine is out of debt. The general manager reports the running of a drift from the Bridal Chamber on the dip of the vein toward the mill for a considerable distance, in rich ore all the way. This development has largely enhanced the value of the mine. Shipments are now being made from the Sierra Belle, and the debt—$45,000—will soon be liquidated, and bullion shipped East. Work is to be vigorously pushed on the Sierra Apache. The Grande company has contracted for smelting works, for its smelting ores, and also for a cupola furnace, the contract calling for their completion within 60 days. The Grande company will then probably purchase the Bella and Apache ores. The rumor of a proposed sale of the Sierra mines to an English syndicate is officially denied by the officers of the company. The rumor probably arose from the fact that an option of a block of stock at $10 per share was purchased by some English gentlemen from Whitaker Wright, a Philadelphia stockholder. The mines will continue to be managed, as hitherto, by the Philadelphia directors, who are acting in a conservative and business-like manner."

TWO whales were captured by the Monterey Whaling Co. last week.

Assay of Silver.

Scorification and Concentration of Silver Lead.

If the lead button is malleable the scorification can be proceeded with direct; but if, on the contrary, it is brittle, from one to three grains of proof lead and 0.3 grain borax glass is added to it on the scorifier, and the operation carried on as before. The scorification is best carried on in a small scorifier made of good fire clay, about eight-tenths of an inch in diameter, ½ of an inch thick in its deepest place, and one-fifth of an inch deep in the center. It is used in a holder made of fire clay, which is partially covered with thick, smooth paper about 2½ inches long and with a hollow place in the top, in which the scorifier fits. A piece of charcoal will also make a good holder, and can be readily cut to the required shape. This is for blow-pipe work, of course, and we take it from a new work on blow-pipe assaying, by George Attwood.

The scorifier is warmed, and when at a red heat the globule of silver lead is added and brought into a state of fusion by the use of the reducing flame. Then the oxidizing flame is used and the heat applied gently. The fluid litharge soon forms, and portions of which adhere and glaze the sides of the cup. The formation of the litharge is greatly assisted by slowly turning the assay round and round from side to side at a gentle inclination, and at the same time keeping the flame at the edge of the bead. When the litharge has once formed it accumulates rapidly, and from 5 to 10 minutes completes the operation. If the ore is poor in silver the scorification can be carried on until what is termed the "eye" appears, *i. e.*, the small button of lead is nearly covered with litharge and only just visible. The operator

Fig. 1.—Cupel in Cupel-Holder.

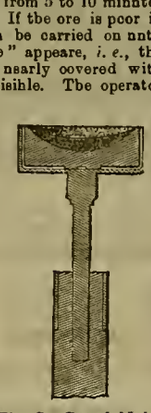

Fig. 2.—Cupel Mold.

can, after a few experiments, decide when the operation should be discontinued. When the lead is rich in silver it oxidizes very slowly and assumes a spherical form.

The assay is allowed to cool, and then the scorifier is broken on the steel anvil and the button carefully brushed. It is then ready for cupellation.

Plattner and David Forbes advise scorification to be partially carried on, on charcoal, after the reduction of the assay, and then finished on a cupel of coarse bone ash. The author has found a loss of silver, as well as an occasional spirting, etc., by the prolongation of the assay on charcoal after the complete reduction of the assay has been effected, and for accuracy and despatch he recommends the above method, as it has been used for some years with success by himself.

Cupellation.

When an alloy of lead, silver, gold, copper, etc., is fused in a cupel in a current of air, the lead is readily oxidized and forms a very fusible oxide. The lead parts with portions of its oxygen to the copper and other base metals. The oxides thus produced are dissolved and carried down into the porous cupel in a liquid state by the vitrified oxide of lead, leaving the silver and gold in the form of a small globule on the surface of the cupel.

The cupellation is conducted as follows: Any lead alloy over five grains in weight is best cupelled in one of the previously prepared cupels placed in the cupel-holder (see Fig. 1). If the weight is under five grains a small cupel is sufficient, which can be rapidly prepared by moistening some of the finely powdered bone ash with enough water to form a dryish paste. The paste is placed in the steel cupel mould, the bottom of which must either rest on the steel anvil or some hard, solid substance, and a cupel formed by placing the butt on the top of the mould and applying a few light strokes. The mould containing the cupel is now dried slowly over the lamp and finally heated to redness, and if no cracks or flaws appear, and the cupel presents a smooth and regular surface, the alloy can now be added (it is never advisable to proceed with the cupellation unless the cupel is found to be perfect), and a mild reducing flame applied, until the assay is in a state of fusion; directly it is so the oxidizing flame must be applied, and the same continued at the outer edge of the globule, and without touching the assay. A strong enough heat must be imparted to the bone ash to keep the assay in oxidation without allowing it to become chilled or quiet. The cupel can also be moved slightly from side to side, which gives the lead a fresh surface of clean bone ash to act upon and facilitate the completion of the operation. It is best to finish the assay about the center of the cupel, but at the same time it is not absolutely necessary for the accuracy of the assay.

With a little practice the operator can tell when the oxidation is nearly finished by the surfaces of the bead being covered with iridescent colors (resembling rainbow colors), which only last but a moment, when the globule rotates and brightens. Directly the colors disappear the heat should be slightly raised, to free the bead from the last traces of lead, and then the assay is cooled down slowly. In assays very poor in silver the latter precaution is scarcely necessary. In the case of rich ores, alloys, etc., much care must be taken in cooling the bead gradually, else a violent sparting takes place, and small particles of silver are thrown out from the bead, and the assay cannot be relied upon, and it should be repeated. When cool the bead is removed by the steel pliers from the cupel and cleaned from any adherent bone ash, and if too small to be weighed it must be very carefully detached by a needle, or some other sharp instrument, and so as not to injure its form. It is then measured or weighed, according to its size; but when the bead weighs more than 0.01 grain it is more correctly estimated by the balance than if measured. In case the ore is very poor, and the button found to be very minute (on scale below No. 10, or 0.11 per cent), it is best to make a duplicate assay and add the first button to the silver lead on the cupel of the second essay, and when finished measure or weigh both together.

The loss of silver by reduction, scorification and cupellation can be corrected by comparing the results obtained from the ore or alloy with those obtained by operating on a carefully weighed piece of proof silver, which is added to an artificial compound, prepared by the operator to resemble as nearly as possible the composition of the ore or alloy which has been assayed. The synthetical assay, so prepared, must be free from silver, with the exception of the amount weighed and added; and it should be fused, scorified and cupelled in a similar manner to the native ore or alloy, and with the same quantity of lead and fluxes.

The difference in weight of the proof silver before assaying and what is found afterwards will represent the loss of silver, and it should be added to the assay weight of the ore or alloy which has been assayed, and it may be considered as the correct loss which has taken place.

Ores and alloys very poor in silver, and so poor that their weight cannot be readily ascertained by the balance, do not require any compensation to be made for the loss of silver in cupellation, etc., as the loss on very small beads is so minute that it can scarcely be estimated with accuracy, and if it could it would be too little to be of any commercial importance.

Most accurate results will be obtained by making synthetical assays and following the methods here described, and the student will find that by adopting the same he can easily make his assays, check them himself, and have perfect confidence in the results he obtains.

Synthetical assays entail more labor and time than that of using tables which have been compiled by authorities on the subject; but it ensures great accuracy, owing in a great measure to the different ways in which different operators use the blowpipe; also to the degrees of heat, apparatus, quality of material, and the fuel, etc., employed.

Process of Smelting Ores.

In the treatment of gold and silver ores containing copper, the object is to obtain a matte, or regulus, which shall contain all the valuable metals. It is, however, found that usually the slag carries off some of the gold and silver which is lost. To obviate this loss, by insuring a more complete separation of the precious metals, many experiments have been made and many processes been invented.

A man named Pearce, of Denver, Col., has devised a method of precipitating the particles of gold and silver held in suspension after the smelting is completed in the usual manner.

An ordinary reverberating furnace is used, and, being charged with mixed ores, the ore is melted in the usual manner. The usual method would be then to draw the slag, and, necessarily, the precious particles held in suspension would pass off with the slag. In place of that, Pearce's method consists in throwing upon the slag, as soon as the charge is perfectly smelted, fine-powdered oxide of copper, then closing the furnace a short time before drawing the slag.

The effect of this application is, that a reaction takes place between the oxide of copper and particles of gold and silver, in whatever combination they may exist, and a rich, heavy matte is formed, which descends and carries with it the precious metals. For a charge of about three tons of ore about 30 lbs. of the oxide will serve the purpose, and on using it care has to be taken to scatter the oxide over a whole surface of the slag. In place of oxide of copper, any rich oxidized copper product may be used.

THE Reno *Gazette* says of the Raphael mine at Downeyville: It has more ore in sight than any other mine on the coast, and is undoubtedly a bonanza.

A MINE in the Organs, New Mexico, was recently sold for $400,000.

A Microscopical Reception.

A microscopical reception was given at the Harmon seminary, at Berkeley, on Friday evening of last week, by the San Francisco Microscopical Society and other microscopists. The reception was held in the large assembly-room of the Institute. The building was crowded with a large and quite select audience, including many of the leading teachers and others from this city. Many were also present from Oakland, while a large portion of the audience was made up from the Faculty of the University, ladies and gentlemen from Berkeley, and the young ladies of the Hermon institute, who filled most of the seats upon one side of the audience-room.

The exercises of the evening were opened by a few words from Rev. S. S. Harmon, Principal of the Hermon seminary, and an invocation by Rev. Dr. Breck. A song, with encore, was then given by the Arion Quartette, after which Rev. Dr. Wythe, of Oakland, was introduced, who delivered a short but very instructive and interesting address upon "The Microscope and Its Revelations." The address was full of interest and instruction, and listened to with the utmost attention. The great importance of the microscope, in connection not only with the study of the sciences, but also as an aid in nearly every avocation in life, was briefly alluded to. While astronomy brings to our notice and treats of the motions and arrangements of great masses of matter, and chemistry explains their constitution, the microscope brings all things to our closest vision, and lets us into the secret of their most minute structure.

The history of the early discovery of the microscope, and its subsequent improvement and gradual adaptation to the progressive needs of sciences and the arts, was happily described. Notwithstanding the apparent complexity of the modern instrument, the principle of the microscope was shown to be exceedingly simple, so much so that the cost of an instrument, well calculated for all ordinary work, was within the reach of nearly every person. The different parts of a perfect instrument were described and distinctly pointed out by the presence of several such shown upon the table in front of the lecturer.

The wonderful power of the modern perfect instrument calls for the exercise of the highest order of brain power, in order to judge and make practical application of the revelations which it makes in the study of minute forms and movements. In this direction the microscope brings us to the very confines of the origin of life, both animal and vegetable. It is beginning to open to our vision the origin of disease, the means of health, and is fast leading us into a field of investigation, which must employ some of the most important and absorbing thoughts which can interest the human mind.

In closing, the lecturer called attention to the character and importance of the interesting entertainment which was to follow, and recommended the study and use of the microscope to all.

After another song and encore by the quartet club, Prof. E. J. Wickson, of the Microscopic Society, made some brief remarks in reference to the character and objects of the society; instructed the audience how to avoid confusion in the examinations which were to follow, and volunteered to lead them through the several rooms in which the instruments with their objects were placed.

The subjects placed on examination were as follows, each instrument being attended by a microscopist, to fully explain and instruct the uninitiated in regard to what was shown: C. W. Banks, micro-engravings; C. H. Denison, diatoms; S. W. Dennis, M. D., dental caries; C. H. Dwinelle, garden and orchard pests; W. B. Ewer, gold in various forms; H. G. Hanks, linen cloth from Egyptian mummy; T. R. Harrold, yeast plant (*Saccharomyces cerevisæ*); Geo. C. Hickox, mineral crystallizations; Arthur M. Hickox, polariscope objects; A. W. Jackson, thin sections of minerals and rocks; W. F. Myers, male and female mosquitoes; F. W. Morse, the phylloxera of the vine; S. M. Mouser, M. D., circulation of blood in mesentery of frog; Prof. W. B. Rising, chemical preparations; F. E. Spencer, diatoms; J. H. Wheeler, California scale insects; G. H. Williams, pond life; J. H. Wythe, M. D., animal and vegetable physiology illustrated; E. J. Wickson, mold of cheese and fruit; C. G. Yale, insects' wings.

The utmost interest was taken by the audience in examining the various objects shown, and in listening to the explanations by the exhibitors. Too much cannot be said in favor of such entertainments. They are not only highly instructive, but also extremely interesting. We have been requested, on the part of the Institute managers, the young ladies of the Institute, and the visitors generally, to return their most hearty thanks to the gentlemen of the San Francisco Microscopic Society for their kind attention shown in providing for them such a truly valuable and instructive entertainment.

C. C. STEVENSON has leased the lower Comstock and Royal mines in Silver City for four years. Mr. Stevenson is to retimber the old working shaft, to erect buildings, put in hoisting machinery, etc., necessary for the successful working of the mines for four years.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 8x10 to 18x60. This latter size furnished J. B. Haggin for Glant and Gld Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. **New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.**

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 8x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery. Chloridizing Furnaces, etc. Mining and Mill Supplies of every description.

WAREROOMS: 92 & 94 Liberty St, New York,

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of **Morey & Sperry** are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of **Morey & Sperry**, will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-class.

MOREY & SPERRY MINING MACHINE CO.

ESTABLISHED 1868.

GOLD SAVED

BY USING MY

SILVER PLATED AMALGAMATING PLATES.

These Plates are used in Quartz, Gravel and Placer Mining with gratifying success. I am constantly filling orders for them, and when once used they prove themselves so superior to any other process yet discovered for saving Gold that my customers would not do without them. I have the best facilities on this coast for filling orders for these plates, and will guarantee my work. Old Mining Plates Bought, Taken in Exchange for New, or Re-plated.

Colorado Iron Works,

MANUFACTURERS OF

ENGINES, BOILERS, RAILWAY CAST AND WROUGHT WORK, BRIDGE WORK, BOLTS AND BOLT ENDS, BUILDING WORK, ETC.

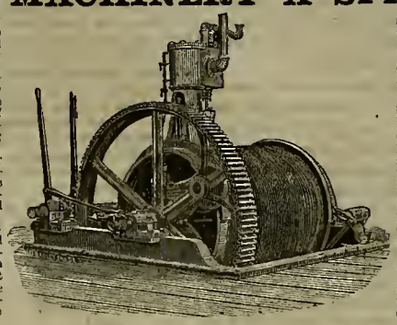
MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the



following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupelation Furnaces, Market Tables, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

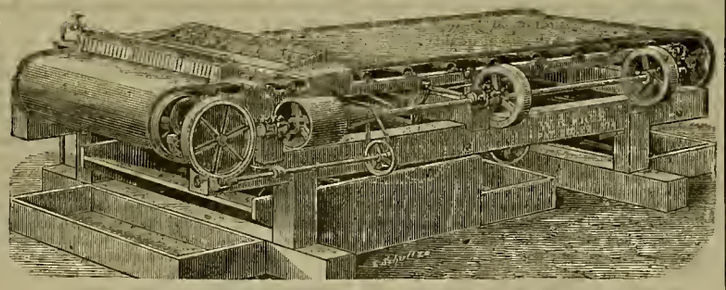
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the **Mechanics' Institute of San Francisco, Cal.**

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of **$1,000** each, and we mean business.

☞ A machine with all improvements can be seen in working order and ready to make tests, at the office of Huckley, Spiere & Hayes, 220 Fremont street.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252, Market St., S. F.

FOR THE WEEK ENDING OCTOBER 10, 1882.

265,655.—ROTARY HARROW—W. T. Browne, Stockton, Cal.

265,769.—FEEDER FOR THRASHERS—M. C. Dillman, Orland, Cal.

265,671.—AIR BRAKE FOR CABLE R. R. CARS—W. W. Hanscom, S. F.

265,681—PIPE JOINT PACKING—O. M. Loveridge, Weaverville, Cal.

265,629.—WATER ELEVATOR—John Patten, S. F.

265,630.—APPARATUS FOR RAISING WATER—John Patten, S. F.

265,700.—FLOWER HOLDER AND STAND—Jos. Perkins, S. F.

265,718—CODLIN MOTH TRAP AND TREE PROTECTOR—Geo. W. Thissell, Winters, Cal.

265,938.—CAR COUPLING—Geo. W. Bedbury, Portland, Ogn.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PACKING FOR PIPE-JOINTS.—Orange M. Loveridge, Weaverville, Trinity Co., Cal. No. 265,681. Dated Oct. 10, 1882. This invention relates to a novel packing for the meeting ends of pipes; and it consists of two metal rings, between which is inserted a leather or other flexible ring or band, a portion of which is folded over on the outer surface of one of the metal rings, the whole being secured together by means of bolts. This is secured in the smaller end of the pipe by means of rivets through the inner ring, the outer ring, with the circumscribing packing-ring, extending from the end, and when said pipe is fitted in the enlarged end of the next pipe said packing ring presses outwardly against the large pipe and makes a tight joint. This invention is especially applicable to water-pipes connected by what is known as a "slip-joint;" and its object is to form a tight joint when the water is turned on and a loose one when it is turned off, and thus to allow ready connection and disconnection of the pipes when necessary, and allow the pipe to expand and contract by the heat and cold without moving on any but the slip-joints.

FLOWER HOLDER AND STAND.—Joseph Perkins, S. F. No. 265,700. Dated October 10th. This is a combined flower holder and stand, and it consists in a basket or other similar and usual receptacle for flower plants, etc., said receptacle being provided with a reservoir for water or earth extending from its bottom, and in a stand or table provided with a central sheath to receive the reservoir of the basket and hide it from view. The object of the invention is to furnish a flower or plant holder which, on account of the provision made for the presence of water or earth, is well adapted to keep the flowers and plants fresh and alive, and at the same time to hide the lower portion or reservoir so that the whole device may bear the appearance of an ordinary flower holder resting on a stand.

CODLING-MOTH TRAP AND TREE PROTECTOR.—George W. Thissel, Winters, Yolo Co., Cal. No. 265,718. Dated Oct. 10, 1882. This invention relates to a device for protecting trees from the ravages of the codling-moth and other destructive insects, and it consists of a table encircling the trunk of the tree at the ground, and having a downwardly-projecting edge which enters the ground, so that the approaching insects will be forced to pass over the table. Around the inside of the table is fixed an annular chamber, which may be filled with cotton or any other suitable substance, into which the insects may crawl. A veil is fixed around the outer edge of this chamber, so that its lower edge will rest upon the table at an angle which will allow the insects to pass inward beneath it and get into the chamber, but prevents their escape.

ROTARY HAMMER.—Wm. T. Browne, Stockton. No. 265,655. Dated Oct. 10. This is an apparatus for striking repeated and rapid blows which the inventor calls a rotary hammer, and it consists of a series of arms carrying hammers at one end, while the opposite end are hinged or pivoted to a revolving disk, by the rotation of which the hammers are carried around in a circle. The hammers strike successively upon the head of an adjustable arm or bar, through which the force of the blows is transmitted to the desired point.

AIR BRAKE FOR CARS OF CABLE ROADS.—W. W. Hanscom, S. F. No. 265,671. Dated Oct. 10. This invention relates to a means for effectually controling the cars and dummies which are used upon street cable railroads, and it consists of a system of brake acting against the wheels and operated by the compression of air, the brakes of the dummy and the following cars all being under the control of the driver.

California Kaolin.

Among the substances of value in this State, which will be utilized in the future, is kaolin, or porcelain clay, such as is used for fine pottery. We have seen some very fine samples of kaolin from deposits in this State, but do not know of said deposits being utilized. Prospectors very often bring in infusorial earth, thinking it is Kaolin, but an investigation with a microscope soon determines this. There is no need of any analysis.

The following correspondence relative to the existence of this substance in California will be of interest:

UNITED STATES CONSULATE GENERAL,
KANAGAWA, JAPAN, Aug. 31, 1882.

Henry G. Hanks—DEAR SIR: In a conversation lately with Mr. Amsden, the latter informed me that you had mentioned to him the existence in California of a deposit of fine porcelain clay. If this is so, will you have the kindness to give me some particulars about it.

I have tried very hard to induce the Japanese at "Seto," the extensive porcelain clay district here, to prepare tea and dinner sets for sale in the United States. They could send and dispose of beautifully decorated sets as cheap as the plain ware is now sold in California. But they are so wedded to their old ways, that it seems impossible to "wake" them up to the importance of such an enterprise.

Now, if the deposit in California is valuable, I will see if I cannot induce a sufficient number of Japanese "decorators" to go to San Francisco and ply their trade there. Having these at command, some of the most beautiful porcelain in the world may be turned out.

I send you by this mail a copy of my reports on "Labor in Japan" and "Porcelain," with a few illustrations.

I hope to be in San Francisco in a couple of months. Your obedient servant,

F. B. VAN BUREN.

OFFICE OF STATE MINING BUREAU,
San Francisco, Sept. 23, 1882.

Hon. F. B. Van Buren, U. S. Consul General, Kanagawa, Japan—DEAR SIR: Your letter, dated August 31st, has been received. There are a number of known deposits of white clay and kaolin in California, specimens from some of which are preserved in the State museum.

The State Mineralogist does not know the extent of these deposits by personal inspection, but has reason to believe that the clays are abundant.

The sample of kaolin sent to you with this is from near Grass Valley, Nevada county, and quite accessible by railroad. The exact locality is section 3, township 15 north, and range 9 east, Mount Diablo meridian.

It is said to exist in a bed six feet thick, with a known and surveyed area of about ten acres. The actual area is unknown. The baked sample of the same (also inclosed), was put in the potters' kiln without washing, or other preparation, by Messrs. Gladding, McBean & Co., who pronounce it to be of excellent quality.

I consider San Francisco to be particularly adapted to the manufacture of porcelain. There being no frosts, it has the advantage of a long dry season, is accessible to the world by sea and rail; borax for glazing is cheap and abundant, which may also be said of all supplies. The manufacture of porcelain would be a benefit, not only to this State, but to the United States generally.

The State Mining Bureau will give you all the information in its possession on this subject. Will send you samples for examination by the Japanese potters, and will aid you in every way in its power in carrying out the plan proposed in your letter. Hoping to hear from you again, and to see you when you visit San Francisco, I remain, very truly,

HENRY G. HANKS, State Mineralogist.

Eureka District Mines.

Several failures of mine stock-broking firms have lately been reported in the city of New York. These failures have been caused mainly through the misrepresentation of unscrupulous promoters, who have succeeded in placing upon the market worthless properties at high figures. Eastern capitalists have not been content to take even chances with poor prospectors, who have spent years of their lives searching in the bowels of the earth for the precious metals. They have claimed that it is not their province to prospect for ore from the surface, but many were willing to pay high prices for mines already developed. Their declarations have brought out a horde of sharpers, who have perfected their plans, and worked the market to the Queen's taste. When will Eastern capitalists learn that mines already developed up to a paying standard are seldom offered for sale until the pay ore gives out? The average miner who is fortunate enough to own such a property, hardly ever cares to sell out, except at extravagant figures, unless it happens that such expensive machinery is needed for the further development of his mine, as is beyond his means to purchase.

It is the general experience in all mines that poor places will occur in them; also, that all ore bodies will give out sooner or later, but no reason can be given why other paying ore bodies will not be found in them while developments are in progress. We, who live in the midst of paying mines, some of them having yielded splendid dividends to their owners, know that it will repay those who have the courage to break ground and prospect for gold and silver, or other metal and ores from the surface of the earth to a great depth, if a reasonable amount of money is expended with due economy and proper judgment. Then, why should men who have money to spare, that they do not need to use in the conduct of other lines of business in which they are engaged, be afraid to risk a few hundred, or even a few thousand dollars, in legitimate prospecting in well-known mining sections? We do not advise people to spend every dollar they possess, but we are sure that Eureka district has within its boundaries thousands of acres of mineral land that if properly prospected can be developed into dividend-paying mines with a reasonable outlay.—*Eureka Sentinel.*

Recording Assessment Work.

An exchange says too little attention is paid to recording, in the County Clerk's office, the annual assessment labor on mining claims. If there were more recording done there would be less litigation. It is true that a "jumper" is required to show that a full assessment has not been worked, but the actual owner is also required to show that the work was done according to law. The value of recording work, however, is most forcibly felt when a sale is about to be made. If the owner, or his agent, is abroad endeavoring to effect a sale, and the title of the property is questioned, reference is at once made to the county records. If the work has been recorded, with other necessary documents, it shows care on the part of the owner. Official record of annual labor has saved many a man's property, and neglect of this duty has lost many valuable claims. There are a hundred and one reasons why every owner of a claim should have his work recorded. Claim owners who are non-residents should be especially particular to have the work recorded, and no contract for assessment work should be let without a clause providing for the affidavit and proof of record. To our readers in the States we call particular attention to this matter. The cost of record is trifling compared to its value. Bear this in mind, or you may some day regret it. As a class, our miners are thoroughly honest, but now and then a scallawag turns up who will accept $100 in payment for $50 worth of work. If he is required to make an affidavit that he has complied with the law before receiving his money he will hesitate a long time before swearing falsely.

The Copper King.

Last week, says the Esmeralda *Herald*, we paid a visit to the famous Copper King mine, Santa Fe district, of which there has been so much talk lately. Of course, from reports, we naturally expected to see a large mine, but not a mountain of ore, as certainly the Copper King is. How for years prospectors have actually worn trails deep into this vast ore body in search of hidden treasures, passing the bonanza by unnoticed, is a conundrum we are unable to answer. T. J. Bradley is the original locator, and about two years ago, for a small consideration, disposed of the mine to Eli Johnson, formerly of Aurora. A short time since Johnson sold to E. B. Burdick, the present owner, for a round sum of money. The mine is situated in the mountain range north of Soda Springs valley, and about seven miles east of Luning. The altitude is 5,000 ft. above sea level, and 1,700 ft. above Soda Springs valley. The course of the vein is northeast and southwest, and lies on the flank of a mountain, having an inclination of 45°. The ore crops out boldly for a distance of 1,200 ft., with an average width of about 100 ft. Within these lines it is utterly impossible to stick a pick down five inches without encountering ore, and that of high grade, too. The mine has been prospected by shafts and tunnel to a depth of about 50 ft., and 1,000 small holes here and there on the surface, samples from which show the handsome average of 18.3% copper. Surveys have been made which give in round numbers 45,000 tons of ore as far as developed, after making the liberal deduction of 25% for horses, barren spots, etc. Putting the ore even as low as 15% the result is $2,295,000. But there is no probability of the ore giving out at the depth mentioned, and it would be impossible to give the amount of ore in the mine (or rather mountain), or come anywhere near it. To give our opinion in brief: It is the biggest and best copper mine we ever saw. A tunnel 300 ft. would tap the ledge at a depth of 400 ft. But ore to run a number of furnaces for a year or two can be breasted from the mountain side at an expense so trifling that it is hardly worth mentioning. Two furnaces with a capacity each of 35 tons have been ordered, and will be put up in the edge of the valley about three miles from the mine. A road from this point to the mine can be built for about $800. The railroad company will run a side-track to the furnace, thus giving cheap rates for needed supplies. Mr. Burdick has secured a spring of water, about three miles from the furnace site, that flows fully seven inches. Thus it is seen that every facility is near at hand to make the Copper King one of the best pieces of mining property on the Pacific coast, if not in the United States, and we congratulate the owner on his good fortune.

Southwestern Nevada.

Important Development of its Mining Interests.

There is considerable travel on the Carson & Colorado railroad just now. Much of this is due to the attention which the mines along the route are attracting. At Mt. Cory and Mt. Grant a number of men are at work, and will be kept busy all winter getting out ore from the different mines. In the spring, a genuine boom is expected in that part of the country. The Downeyville mines are showing up new developments every week. The ore is immensely rich, and is mostly silver. In Garfield district, prospectors are still actively at work. Several of the claim owners have been offered good prices for their properties, but they do not appear to be on the sell. At Candelaria, the Northern Belle mine is producing ore of extra quality. The new strike made by Supt. Bobby Jones, just before his death, is widening out, and the ore is of higher grade than any taken from this mine for a long time. Supt. Price, who now has charge of the mine, has a good force of men employed, and is working the ledge for all it is worth. Considerable is also being done in some of the other mines. The trip from Virginia City to Candelaria is made in just 12 hours—leaving here at eight in the morning, and getting there at eight the same evening. There are two good eating-houses on the road, one at Wauknska, kept by Mr. Lovejoy, and the other at Soda Springs, by Mr. Davis, formerly of Carson.

All along the route strangers are received cordially, and the people appeared to be pleased to give such information concerning their country and its resources as may be of interest to travelers. Southwestern Nevada has a bright future. It is destined to become, if not the most prosperous portion of the State, at least as prosperous as any other part, and that at no distant day. Its increasing wealth and importance is already attracting the attention of capitalists, and its population is rapidly growing.—*Enterprise.*

AGRICULTUTAL DEPARTMENT STATISTICS.—The Department of Agriculture reports that the average yield of oats will be somewhat higher than last year or in 1879. The product is nearly as large as that of wheat, probably about 480,000,000 bushels. The yield of rye, averaged from State returns, is 14 7-10 bushels, making a crop of 20,000,000 bushels, or nearly the same as reported by the Census Bureau. The indicated average yield of barley is about 23 bushels per acre, aggregating 45,000 000 bushels. California, New York and Wisconsin together produce more than half, or 27,000,000 bushels. The product in 1879 was 44,000,000 bushels. Buckwheat is good for nearly an average product of 11,000,000 to 12,000,000 bushels. The average production of potatoes is 81 per cent. Returns indicate a probable yield of 80 bushels per acre on an acreage of nearly 2,000,000 acres. The total value of exports of domestic breadstuffs during the nine months ending September 30th was $134,512,779, and for the corresponding period of 1881, $177,453,638.

SLACKING LIME FOR MORTAR.—The marvelous durability of mortar in Italy is attributed by the London *Builder* to the fact that the lime remains in a pit covered with water for two years before it is used, whereas in England and in this country lime is slacked and used the same day. Most building specifications even require newly slaked lime.

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,

No. 252 Market St., S. F.

Old Papers Wanted.

Twenty cents each will be paid for a limited number of copies of any of the following Nos. of the MINING AND SCIENTIFIC PRESS, if received soon at this office: No. 1, of Vol. 13, 1866; No. 5, Vol. 18, 1869; Nos. 1 and 26, of Vol. 20, 1870; No. 1, of Vol. 22, 1871. Also, 10 cents per copy for Nos. 2, 3, 4, 7, 10, 11, 12, 13 and 15, of Vol. 30, 1875. If any one who has files of back volumes of the PRESS, which they may like to dispose of at a moderate rate, will send us a memorandum of the same and the price, we may be able, sooner or later, to assist in their disposal.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

Mining and Other Companies.

Pereone interested in incorporatione will do well to recommend the publication of the official notices of their companies in this paper, as the cheapeet appropriate medium for advertising.

DIVIDEND NOTICE.

OFFICE OF THE

Northern Belle Mill & Mining Company.

San Francisco, October 16th, 1882.

At a meeting of the Board of Directors of the above-named Company, held this day, Dividend No. 65, of fifty cents (50c) per share, was declared, payable on MONDAY, October 16, 1882, at the office in this city. Transfer books closed Wednesday, October 11, 1882.

WM. WILLIS, Secretary.

Office—Room No. 29 Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

IRON MINE FOR SALE.

An Iron Mine of three claims consolidated, situated two and a half miles from Rutherford, on N. V. R. R. Contains very large body of high grade ore, samples of which may be seen at this office. For particulars address,

MRS D. S. ROHLWING,
St Helena, Napa Co., Cal.

Fair Premiums.

W. H. OHMEN,

MECHANICS' FAIR, 1882.

Vertical Engine and Boiler Combined.....Silver Medal.
Vertical Engine.....Silver Medal.
Hoisting Engine and Boiler Combined.....Bronze Medal.

Engine and Machine Works,

109 & 111 Beale Street, - SAN FRANCISCO.

☞ Hoisting, Upright and Horizontal Engines and Boilers a Specialty.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder

NO. 1. The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work

JUDSON POWDER

is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞ The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50 to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

THE CONSUMERS' COMPANY.

VULCAN B B,

The Best Low Grade Explosive in the market. Superior to Black or Judson Powder

VULCAN NOS. 1, 2 AND 3,

The best Nitro-Glycerine Powders manufactured. Having secured large lots of the best imported Glycerine at low prices, we are prepared to offer the mining public the very strongest, most uniform and best Nitro-Glycerine Powder at the very Lowest Rates.

SPECIAL INDUCEMENTS IN PRICES.

Vulcan B B Powder (in Kegs or Cases) is Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

The Central and Southern Pacific Railroads Use Vulcan Powder and no Other.

1850. 1882.

RANKIN, BRAYTON & CO.,

127 First St., San Francisco, Cal.

BUILDERS OF

MINING MACHINERY.

Plants for Gold and Silver Mills, embracing the latest and most improved machinery and processes for base and free ores. Water Jacket Smelting Furnaces for silver, lead and copper ores, with new and important improvements, superior to any other make. Hoisting Works, Pumping Machinery, Chloridizing Furnaces, etc. We offer our customers the best results of thirty years' experience in this special line of work, and are prepared to furnish the most approved character of Mining and Reduction Machinery, superior in design and construction to that of any other make, at the lowest possible prices. We also contract to deliver, in complete running order, Mills, Furnaces, Hoisting Works, etc., in any of the Mining States and Territories. Estimates given on application. Send for illustrated circular.

This cut represents a No. 1 CALF SKIN SHOE, made in GAITER or LACE, all sizes, which we are manufacturing with a view to meeting the wants of a large class of people who must have the best shoe for the least money. It is guaranteed as to STYLE, FINISH and QUALITY, and will compare favorably with any $5 shoe in the market. In order to introduce our goods, we will send FREE to any address for the low sum of $3.85 a pair, thereby saving to the consumer the large profits of the jobber and retailer. TRY ONE PAIR AND BE CONVINCED.

F. H. WILSON, 232 West Baltimore St., Baltimore, Md.

KNIGHT WATER WHEEL

All sizes of this Superior Wheel furnished at the shortest notice. Send for circulars to

ALMARIN B. PAUL, Agent.

Room 20, Safe Deposit Building, San Francisco, Cal

Engineer and Machinist.

WANTED.—A position by a first-class engineer and machinist. Understands all kinds of repairing on water jackets, smelting furnaces, boiler works, etc. Address, W. F., this office. First-class man, used to mining or milling work.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenifurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequaled by any other published embracing the subjects treated. Post-paid, $7.50. Printed and sold by Dewey & Co., S. F.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, OCTOBER 28, 1882.

VOLUME XLV Number 18

Placer mines.

The amount of skill and capital necessary for the successful prosecution of placer mining is usually less than is requisite for carrying on quartz mining, on a remunerative scale; and placer mines are generally those to which attention is first directed in a new country, and from which remunerative returns are most readily obtained.

Placer claims are spoken of as sluice, hydraulic, drift and tunnel claims, dry diggings, etc., in accordance with the means employed for reaching the auriferous deposits, and the methods adopted for the separation and collection of gold. In the early days of California and Australian gold mining, when paying diggings could generally be found near the surface, and before the large deposits of pay dirt lying at great depths below the ground had been discovered, the greater portion of the gold produced was obtained from shallow workings. These have now to a great extent become exhausted, and in Australia shafts are sunk to the old deposits, whilst in this State dams and ditches have been constructed, and hydraulic mining is extensively introduced. In both countries, therefore, at the present time, the greater portion of the gold obtained is the result of deep mining, the shallow placers being generally abandoned to the Chinamen, who are satisfied to wash over the dirt which has been already passed through the machine, or has escaped the attention of the ordinary miner.

The object of the miner is generally to obtain the largest quantity of gold in the shortest possible time, and with the least amount of labor and expense, rather than to extract the total amount contained in the material on which he operates, and consequently, without taking into consideration the necessary loss, incident to the imperfect nature of the appliance employed; his refuse will naturally retain a certain proportion of the gold originally present. The falling abroad, of lumps of clay, by the action of the weather constantly exposes fresh particles of the precious metal, and from this cause the residues frequently afford an amount of gold that could not have been otherwise obtained from them. Many contrivances have been introduced with a view to obtaining the whole, or a large proportion, of the gold present in the pay dirt, but, in the majority of instances, the result has been a failure; and if an increase of yield has sometimes been obtained, the additional gold extracted has frequently been more than compensated for by the extra expense entailed.

Whilst the supply of shallow auriferous dirt was sufficient to furnish employment for the whole laboring population, the gold produced was almost exclusively obtained either by solitary diggers, or by small private companies of workingmen, whose capital consisted rather in their united strength than in an accumulation of money. Things went on in this way until the richer and more easily-worked alluviums had become partially exhausted, when it was found that to carry on successfully the deeper diggings, combination in a somewhat more extensive scale became necessary, and that capital and intelligence, as well as strength and endurance, were required by the gold miner.

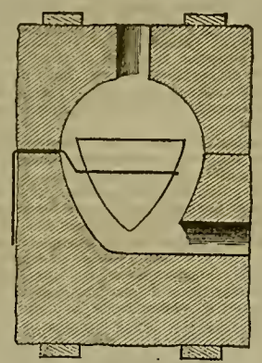
In this way the uses and exigencies of a newly discovered gold region rapidly changed and became more assimilated to those of more commercial and longer established communities. A lucky miner became a capitalist, and in the gold regions, as in other places, money commands labor, and large operations are commenced, often to the doubtful advantage of the speculators, but to the manifest benefit of the general community.

For the 30 years ending 1880, the money invested in mining for the precious metals—buying mines, labor and machinery—is estimated at $700,000,000. For this expenditure we have a return of values—values that can be converted into cash at sight in mines, mills and actual cash received, $2,200,000,000, which is over 300% on the investment as actual profit.

Fusion for Black Copper.

Fusion for black copper is conducted in Sweden in the blast furnaces of the form represented in the accompanying engravings. These are about 17 ft. in hight, and three ft. in diameter at the twyers; and a portion of the gases are taken off from these furnaces about eight feet below the hearth. Such a furnace being charged with 200 lbs. of the regulus from the last operation, 40 lbs. of roasted thin regulus (a regulus produced in a previous smelting for black copper), 20 lbs. of ore furnace slags, 20 lbs. auriferous products, and from 10 to 20 lbs. of quartz, according to the amount of silica already present in the mixture. The furnaces worked with a twyer prolongation or nose, of from four to six inches in length, and the breast of the furnace is closed with sand, except a small opening through which the flame blows during the working of the furnace.

The products of the operation are black copper, so called from its black oxidized surface, which corresponds in composition very closely to the "blister copper" produced in the Welch method of smelting. This is accompanied by a superstratum of thin regulus or mat varying,



Charcoal Blowpipe Furnace.

according to the proportions of copper, from reddish-blue to steel-grey in color, and containing from 55 to 72 per cent. of copper; this regulus, after roasting, being added to the charge of the same furnace in subsequent fusions; and forming the upper stratum is black copper slag, a portion of which is also returned to the furnace with future charges; while, lastly, there collects in the hearth of the furnace ferriferous masses or hears, like those described as occurring in the ore furnace. It is for utilizing the waste heat of the furnace, and, at the same time, to prevent, as much as possible, the formation of these masses, that the gases are drawn off from the furnace.

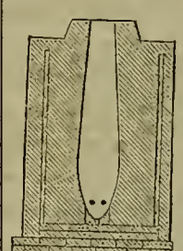
When the melted matters in the hearth of the furnace reach almost to the twyers, the slag is drawn off into sand moulds, by removing a portion of the breast work of the furnace, after which the breast is made up again and more materials are added to the furnace with tapping of the slag as before, until a sufficient quantity of black copper and regulus have collected in the hearth as to require tapping-out, which occurs every two or three days; upon which the slag and regulus are drawn off close to the surface of the black copper, and the metal is tapped into a long iron channel divided into a number of compartments, forming a series of moulds in which the copper is cast. Any regulus which runs out with the slag will collect beneath the first few pigs, which are turned over as soon as solidified, and while still hot are broken, whereby the regulus is easily separated from the slag.

Leadville will pay this year to the railroad companies of the United States $1,000,000 for the transportation of bullion to the Eastern markets. She pays as much more for freight on ore, coke, machinery and mining supplies.

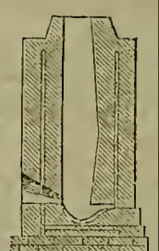
Position of Tuyeres in Furnaces.

At a recent meeting of the Institution of Mechanical Engineers at Leeds, the question of the working of blast furnaces of large size at high temperature with special reference to the position of the tuyeres was considered. A paper on the subject was read by Mr. Chas. Cochrane. According to his statements the investigations during the past 10 or 12 years into the working of blast furnaces in the Cleveland district had been chiefly directed, in the case of furnaces of various capacities and employing various temperatures of blast, to comparing the fuel consumed per ton of iron made, and the temperatures and relative production of carbonic acid and carbonic oxide at the tunnel head.

From these investigations conclusions had been drawn which were not favorable to the employment of either very large furnaces or very high heats, an impression having once been very general that a furnace of 12,000 cubic feet capacity, and with a temperature of 1,000° Fahr., was in the most favorable conditions for successful working in the Cleveland district. In all the discussions which had taken place it would appear that two important elements in the successful working of a blast furnace had been overlooked or altogether ignored—namely, the size of the hearth and the overhang of the tuyeres; or, as it might be put, the distance of the tuyeres apart across the hearth. The experience gained by the writer pointed to the fact that in the employment of high temperatures of blast the distance of the tuyeres apart



Vertical Section in Front of Tuyeres.



Vertical Section Through Tuyeres.

from nose to nose was of great consequence, and that if they approached too close the effective capacity of the furnace was materially reduced. The reduction might easily go so far as to destroy the economy which should have resulted either from extra cubic capacity of furnace or from extra temperature of blast employed. In this way a furnace of 20,454 cubic ft. actual capacity has been lowered to only 12,000 cubic ft. effective capacity, and the consumption of coke had been increased from about 21 cwt. to about 25 cwt. per ton of iron made; in other words, a furnace of only 12,000 cubic ft. actual capacity, working efficiently would have done as good duty as the furnace of 20,454 cubic ft. capacity actually did. Mr. Cochrane then proceeded to give the results of experiments made by him on four-blast furnaces.

In one furnace which he mentions, the tuyeres of which, till the end of January last, had been only six feet apart, and during the months of February and March were separated to a distance of seven feet apart, the following results were obtained: The make, which had been limited to an average of 483 tons per week over the preceding months of November, December and January, rose in March to 599 tons per week, whilst the gross consumption of coke was only increased by 27 tons, or from 603 up to 630 tons per week. The tuyere area was unaltered, being 141 square inches total. The temperature of escaping gases at the tunnel head in March was 100° Fahr., less than before the withdrawal of the tuyeres, namely, 617°, whereas previously it had been 717°, whilst the temperature of blast was increased by 109°, being 1,321° in January and 1,430° in March. The result of drawing back the tuyeres was to prevent the centralization of heat, and to bring about a uniform, or the more nearly uniform, distribution of the ascending gases over the whole transverse sectional area of the furnace. In the course of some remarks made by Mr. Cochrane after the paper was read, he said the drawing back of the tuyeres to the extent of 6 inches was worth annually 3,000 in the saving of fuel alone. Mr. I. Lowthian Bell differed from some of the conclusions arrived at by Mr. Cochrane. Alluding to what he submitted was an error of Mr. Cochrane's in setting down in his so-called curves of effective capacity the performance of 20,400 cubic feet to one of 12,000 cubic feet because it consumed 25 cwt. of coke per ton of iron, he said that a unit of coke burnt in one of the Clarence furnaces of 11,500 cubic feet actually evolved more heat than Mr. Cochrane was obtaining in a furnace more than twice its size with blast 400° or 500° Fahr. hotter. This was entirely the result of a more perfect combustion of the fuel at the Clarence works.

New Mexican Mines.

We have been shown by Mr. Madera, who has just come from New Mexico, some specimens of ore from the Black range, N. M., where the now famous Lake Valley mines are located. A piece from the big lump, which contained $80,000 is almost solid silver, and the silver can be melted right out of the rock.

A piece from the Bullion mine, belonging to a subscriber of ours, Mr. Chapman and others, looks like ore from the Comstock. It is black sulphurets, and runs some $3,000 per ton.

Float ore from Governor Talor's mine contains horn silver, and is, of course, very rich. This mine is called the Solitaire, and is being worked very successfully. Gov. Perkins, George Hearst and Messrs. Head and Burns own a mine called the Superior. It adjoins the Bullion. The ore runs about $420 per ton. The mine is being very rapidly developed.

A piece of ore from the Bremen silver mine, 30 miles from the other mines, is very peculiar. The gange is heavy spar and seems to be shot through with bullets of silver. The formation is very irregular. The bullets of sulphide of silver are plentifully sprinkled through the ore, but each is isolated. This mine is turning out well now and paying handsomely. This mine belongs to one of our old subscribers, Mr. Bremen.

The Santa Rita copper mine, at the head of the Mimbres river, belongs to the Calumet & Hecla Mining Co., of Lake Superior. Large masses of pure copper are found. The main part of it is in solid sheets, but some of it is shot copper. The specimens we examined are very fine indeed and of remarkable appearance. There are extensive works at this place. They have a 20-stamp mill and Cornish rolls and a system of digs, etc., the same as at the Calumet & Hecla, of Lake Superior. They are using a reverberatory furnace, and also a California Water Jacket furnace, made by the Pacific Iron Works, of this city. The mine is working very prosperously.

We shall next week give a map of this new mining region, and some more detailed description of the principal mines.

Charcoal Furnace for Blow-pipe Assaying.

We take from George Attwood's work on "Practical Blow-pipe Assaying" an engraving illustrating a charcoal furnace made out of two sound pieces of charcoal. The inside is bored out by means of a borer, like the reamer used by carpenters. The blast hole and escape way is made by a smaller borer.

The crucible, already charged, is placed in the furnace, and held in its place by the platinum wire. The furnace is then held securely by the holder; the flame is applied through the blast hole—at first a gentle flame, then a strong, reducing flame. Flames will soon be seen to issue from the top hole, and by looking into the same, the operator can see whether the assay is fused or not. If it is found to be fused, give it a strong blast for about one minute, and then allow it to cool. The crucible, when cool, is broken, and the lead button cleaned. The slag must be examined, and if a perfect fusion has not taken place the assay must be repeated,

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Wallapai Mining District, Arizona.

I have just made an extended trip through this district, and I am surprised to see the number of large rich veins, and the amount of ore lying idle on the different dumps, when, if it were in any other section of country but the northwest corner of Arizona, it would not he idle a week. I defy anybody to show me such a district and so little doing. Why is it? I am satisfied of one or two things, and one is, parties hold their property too high, and another is, the majority own too many claims, and it keeps them poor doing assessment work. There are a great many who are owning claims and have never done any work on them themselves, and they will not let anyone else do any, for the reason they

Relocate from Year to Year,

And the consequence is there are no developments. I will mention one striking instance. A party held and relocated a large ledge for years, and never put a pick in it; but the 1st of last January another party outwitted the old outfit, and they located it and called it the Alpha. They went to work on it like men, and now have a shaft on it 75 ft. deep, with a pay streak over three feet in width, that averages over 150 ozs. in silver. They have on the dump over 80 tons of ore that will work 150 ozs. in silver. It is chloride and black sulphurets carrying considerable copper and lead. Three and one-half pounds of the ore (a sample of ledge at 15 ft.) which was sent to Prescott to be assayed went $6,500 in silver. Now that is only one instance. I would be pleased to give you a

General Description of the Mines

And ledges in that vicinity and in the district, and it ought to be done in justice to it and the miners who have worked and are waiting the advent of the A. & P. R. R. At this writing I will simply give a brief description of some of the more prominent ledges in it. In the immediate vicinity of Stockton are 10 ledges, which will average in width from five to 15 ft. Prominent among them are the Sixty-three, Mocking Bird, Cupel and Tiger, Infallible, Star Spangled Banner, Pioneer, Miners' Hope, Tigress, Cincinnati. The ore in any of these will average 80 ounces in silver. The Mocking Bird is at present worked by A. S. Bush on lease. There is a shaft 140 ft. deep. There are two or three other small shafts and a few short levels and one level run on the ledge over 150 ft. in length. At this point the ledge is about three feet in width. The pay streak is smell but rich; five tons of the ore, assorted, milled at $550 per ton. The Sixty-three is a famous ledge. It has produced more money than any other mine in the county. It was owned by parties in San Francisco, and got to be a subject of litigation. It was badly managed, finally relocated, and now there is a party working it on a lease, who shipped some of the ore to San Francisco about a month ago, which was sold there at $783 in silver per ton. He has now a few tons at the Mineral Park mill, which will work at least $1,200 per ton.

The Cupel and Tiger is a large and well-defined vein, and has produced several thousand dollars from ore which has been shipped to San Francisco. It belongs to Spruance & Stanly, of your city. There are at least 75 tons of ore on the dump, which will average 200 ounces of silver per ton. Four average assays, recently taken from four different parts of the mine, went as follows:

	Silver.
No. 1, 50 ft. from surface	$365.87
No. 2, 85 ft. from surface	151.00
No. 3, 105 ft. from surface (bottom of shaft)	677 00
No. 4, open cut	691.70

Wherever the mine has been opened it looks first-rate.

The Infallible, owned by McKenzie, Hate & Co., old miners and prospsotors, has several tons of ore on the dump, which will work 100 ounces in silver per ton.

The Star Spangled Banner is a gold ledge, and a good one. Considerable work has been done on it, and there is ore on the dump. The Pioneer is a very large, strong vein, owned by Kenedy & Potts, who, for poor men, have done a great deal of work to develop it. The ore is low grade—$60 to $80 per ton—but they have any quantity of it. When we can work that grade of ore in the district there will be "millions in it." The Miner's Hope is a ledge 14 ft. wide. The pay streak is about three feet, which averages and works from 80 to 200 ounces per ton. It has a shaft about 75 ft. deep. The Tigress is another large vein of low-grade ore. The Cincinnati is a large vein, and a great deal of the ore is high grade, carrying lead and antimonial silver, but it belonged to some parties here and in New York, and it was a poorly managed affair; so it lies idle. They have considerable ore on the dump.

Those are a few of the mines about Stockton. Then here is a few of the mines in the vicinity of Lane Springs, Alpha, Indian Queen, Ural, Snow Flake and Warnes. The Alpha I mentioned in the first of my letter. The Indian Queen is the southeast extension, has a shaft 50 ft. deep, and the owners are still sinking. It looks fine, and they have plenty of good ore.

The Ural is the northwest extention of the Alpha. The owners are running a tunnel on the ledges; they have worked but 10 days, and have about 10 tons of ore on the dump, which averages 100 ozs. in silver.

The above goes to show what a fine property the Alpha is to be lying dormant so long. It now belongs to W. V. Cole & Co. The Snow Flake is another large and fine ledge. A party has a lease on it; they are taking out some fine ore; have about 10 tons on dump; average of ore streak from assays recently made is $153 28, 30% lead. The Warner is the west extension of Snowfleke, has an open cut on ledge and about 15 tons of good ore on dump.

In my next, I will give you the balance of the district. There is Tod Basin, Bob Tail Basin, Mineral Park and Cloride to hear from yet; still they say we have no country. Those who say so have neither sense, judgment nor money. Yours, W. H.

Mineral Park, Wallapai, Arizona.

Early Day Mining.

The Quartz Mills of Nevada County in 1852.

Mr. Melville Atwood, who was among the first of mining men, both as to ability and in point of time, who ever came to Grass Valley, gives us a list of the quartz mines that had been built or were in progress of construction in the month of September, 1852. The list was prepared by Mr. Gil. Meredith, who was then a resident of Grass Valley, and whom some of our older citizens remember. Meredith was, not long since, killed by a railroad accident which occurred somewhere in the East.

It will he seen by the list of mills of 1852 that quartz mining in this country was confined then to Nevada City and Grass Valley mining districts: Since then some quartz mining has been done in Eureka South (Granitevills) and in Washington districts, but most of the quartz mining is done, as it was 30 years ago, in the two districts first named. We give the list of the mills that had been built and their condition up to some time in September, 1852, in Nevada county:

Grass Valley District.

Empire quartz company, steam power, 10 stamps, running.

Rocky Bar, Chili mill, steam power, failed.

Nevada county gold mining company, steam power, 10 stamps, running, using the Stockton patent.

Conway & Preston's mill, 18 stamps, steam power, running.

James Glenn's mill, 10 stamps, running.

Grass Valley quartz mining company's mill, steam power, 6 stamps, running.

Gold Hill quartz mining company's mill, steam power, 18 stamps, running.

Union Hill quartz mill, steam power, 24 stamps, running.

Pacific quartz mill, steam power, 18 stamps, running.

Park's quartz mill, steam power, 10 stamps, running, using the Stockton patent.

Bacon quartz mill, steam power, 10 stamps, running, using Stockton patent

New Orleans quartz mining company's mill, steam power, 10 stamps, awaiting machinery.

Van Emmon's mill, water power, no water and failed.

Kelly's mill, water power. No water and failed.

Grass Valley gold mining company's mill, steam power, 10 stamps, not running.

Whitesides' quertz and sawmill mill, water power, 10 stamps, no water.

Nevada City District.

Gold Run mill, steam power, running.

Telegraph quartz mining company, steam power, 18 stamps, failed.

Central quartz mining company, steam power, 24 stamps, failed.

Bunker Hill quartz mining company, water power, 10 stamps and furnace, running.

Wyoming quartz mining company, water power, 10 stemps, running.

Western quartz mining company, steam power, Chili mill, not running.

Revere quartz mining company, steam power, 15 stamps, not running.

Ural quartz mining company, steam power, 18 stamps, waiting for machinery.

Ural No. 2 quartz mining company, in process of construction.

Tremont mill, steam power, 24 stamps, failed.

Gold Tunnel mill, steam power, 10 stamps, failed.

American quartz mining company, steam power, 10 stamps, failed.

St. Louis quartz mining company, steam power, 18 stamps, waiting for machinery.

Washington mill, steam power, 18 stamps, running.

Rodgers' mill, steam power, 5 stamps and furnace, failed.

There was also a mill, water power, name unknown, with 9 stamps, not working, and a Chili mill, owner unknown, not running.

A few years ago copper ledges in Arizona were valueless. They were passed over by the prospector in his search for the more precious metals without a thought. They were not worth the trouble of locating and recording. The advent of the Southern Pacific railroad has wrought a change in all this, and to-day the copper mines of Arizona are attracting full as much attention as her silver honanzas, and are proving full as profitable as investments.

Forest Trees of California.*

Douglas Spruce.

(*Pseudo-Tsuga* [*Abies*] *Douglasii*).

"There is a quiet spirit in these woods."—*Longfellow.*

Douglas spruce is found in great abundance in California and Oregon, from coast to Rocky, Blue and Sierra mountains, but does not climb the higher and highest elevations, yet ranks among the grandest of the lofty and exceedingly beautiful trees of the Pacific. This is one of the first and best known trees of the far West, discovered by Menzies, at Nootka sound, in 1797, during the voyage of Vancouver, afterwards by Douglas, and truly identified, and in whose honor it received its final specific name. It has been well described and renamed by many authors up to the recent date of the last publication. This tree constitutes a large portion of the heavily wooded timber lands of the coast and lower sierra. A short time ago, on the Central Pacific railroad, about 3,000 ft. altitude, were to be seen specimens about 200 ft. high, 9 to 10 ft. in diameter, and some 15 ft. In closely crowded forests they are even higher, reaching 300 ft. Here the trunk often forms a column straight as an arrow, with scarcely a branch for from 100 to 200 ft. Like most trees of dense forests, our conifers are colonaded and towered, so that it is rare to find trees spreading or even well spired continuously from base to summit, as seen under cultivation. We notice, however, on the most broken coast those species of spruce and firs that climb the tallest steepe suited to their habit, and are, least of all, liable to be shut off from abounding sunlight and air, are those that retain their branches long; a few such sentiments, outskirting the crowded plateau forests, also are found of exceedingly great beauty; the branches from horizontal at length droop in graceful curvse with ascending star-spangled sprays, and these in softened slightly silvery tips joyously upturned like the bent bow on its back, wooing the hand of some primitive Nimrod, thus, in due order, multiplying and successively aspiring, feathery and flossily thickened in with foliage of unwonted delicacy and grace inimitable. And again, where we see them thriving luxuriously upon moderate mountain elevations of free outlook, favoring soil, sun and aerial conditions most conducive, as upon the lower mountain ranges contiguous to the base of Mount Shasta, its intrinsic native grace is greatly hightened to one's beau ideal of princely elegance and beauty. Witness those most extraordinary steamer sprays, 17 to 18 ft. long, of similar slender size, of plumed curtain cords, drooping vertically, like the Bridal Veil fall, in Yosemite; or say, what could exceed the stately grandeur with such a softened and graceful flow of sylvan elegance, as is displayed by this truly "Vernal Fall" of the forest? Nor is this exuberant sport all of the "witch knot" origin of Scottish renown, but, like that of the Sitka spruce, must chiefly spring from more highly enriched soils and favoring influences indicated.

The bark on older trees is dark brown, thick, coarse and rough; water-ways deep, flaring, or gaping, often broken and confused, and the general longitudinal fissure plan so jumbled as to bewilder the eye. In veteran forests they are more or less charred by periodical fires—not always the wanton work of man—for we have seen, several times in a single season, the scathing fires of heaven gleaming from clouds envelop lofty trees hundreds of feet high in one unbroken column of blaze, a perfect tower of fire, leaving the forest burning in its tracks months afterwards, or until the rainy season set in and stayed the raging. Strangers seeing many steeple-topped trees—spruces, firs, pines and cypresses, especially in the young state, are apt to hastily infer this to be peculiar to California forests; whereas, we have really a greater number of flat heavy-topped conifers than are seen in the Mississippi valley.

This timber is exceedingly tough, rigid, and bearing great transverse straight, though coarse-grained from the best localities lasting: for long timbers of great strength, much sought after, *e. g.*, those very long mining pump-rods, 60 ft. to 200 ft. long—in some cases 2,400 ft. or more long, the rod alone weighing many tons, counterbalanced by transverse walking beams every 200 ft. or so. These solid timbers are about 16 inches square. For bridges, frames and strong rough work generally of every kind they are most superior.

For butter and similar boxes, that require to be sweet and odorless so as to communicate no taste or flavor to their contents, the wood is invaluable. It is the well-established opinion of experienced lumbermen and miners, mechanics and farmers, that the timber is best within its middle belt, say 3,000 to 4,000 ft. altitude of northwestern and western exposures. Of course this altitude given is not absolute, but applies mainly to California from the north line of Mexico to Oregon. Besides other superior qualities, it may be noted this timber is not so hard to work, etc. In higher latitudes the isothermal lines dip lower toward the coast, and the average requisite temperature, rainfall, etc., accord the best conditions of vigorous growth. Lower down the mountains this tree is not at all equivocal. Far south the wood is red, more brittle, splits too easily, fails to hold the spike as good timber will unrentlessly; it is, however, said to be lasting. A tree so well known requires little detailed description. Suffice to say: The spruce leaves are narrowly line-like, about one inch or so long, furrowed above, keeled below, margins smooth, recurved, and a little bluish bloomy beneath; cones pendent from near the tips of twigs, long egg form, nearly sharp pointed, three to five inches long or so, and about one or two inches in diameter; scales few, large, loose—hut not shed off like firs—roundish, entire and thin; the bracts above strap-like, projecting out beyond the scales lying along the surface, and pointing toward the tip of the cone, ending in three points, of which the middle narrow one is the longest. Sabin describes the cones as erect, whereas they are pendent. Nuttell's figure represents the bracts reflexed; they are not so, but as we sketched them in Vol. VI, U. S. R. R. reports, page 34.

The recently discovered large cone (*Macrocarpa*) variety(?) of San Philipe canyon and elsewhere in the southern part of the State and Arizona, perhaps requires more than mere enumeration. The form of this tree is rather more broadly conic, branches more horizontal, open and airy in appearance, leaves longer; cones, scales and seeds larger, etc. This large tree attains to 100 ft. or more high, 5 to 6 ft. in diameter—quite as much diversity from the type as the restored *Pinus Jeffreyi* from the old *ponderosa*.

Woodmen and workers distinguish this one species into two kinds (or qualities?), red fir and yellow fir; the former with red, hard, brittle and knotty heart of matured wood; singular enough, and contrary to the usual custom with other timbers, this heart wood, by common consent, all reject as relatively worthless. The other kind has softer wood, with scarcely a feeble tinge of yellow; this is easier worked and highly valued, but deemed less lasting. Much more appropriate common names would be red and yellow spruce.

* From "The Forest Trees of California," by A. Kellogg, M.D. Published by the State Mining Bureau, State Printing Office, Sacramento.

A Good Mining Section.

Some time next February the Careon and Colorado railroad will reach Benton. It will then be in the midst of a good mining section, and as it progresses will continue in a fine region for prospectors. Next Spring there will doubtless be quite a rush into this region, and many valuable discoveries will be likely to be made. Already a good deal of mining is being done in that region. An Inyo *Independent* correspondent says: Clover Patch is situated within ten miles of Benton. The principle mine in the district is the Banner, owned by J. McDermott, P. Dowd, J. Lewis and others. They are building a five-stamp mill, and intend adding five stamps more next spring. The mine is in a granite formation, with porphyry and limestone walls. The ledge trends northeast and southwest for a distance of seven to eight miles, and from three to 40 feet in width. There are some 30 locations on the main ledge. The banner ore is free milling, and assays from $20 to $150 per ton; general average about $50. The company have about 500 tons of fine-looking ore on the dump. Twenty men are employed at the mine and mill. The Shay mine is situated on the northern end of the ledge, and was discovered in 1876. The main ledge is from 16 to 18 feet in width, with from 10 inches to two and a half feet of solid ore. The north and south extensions of the Shay mine are owned by Thomas G. Kelty and others of Benton, who are doing considerable work on them. The ore is about the same character as that of the Shay mine, and assays from $15 to $75 per ton.

PROTECTION FOR THE MINERS.—The following is the law: "Any person, corporation or association, or the agent of any person, corporation or association, engaged in the milling, sampling, concentrating, reducing, shipping or purchasing of ores in this Territory, who shall, in any manner, knowingly alter or change the true value of any ores delivered to him or them, so as to deprive the seller of the correct value of the same, or who shall substitute other ores for that delivered to him or them, or who shall issue any bill of sale or certificate of purchase that does not exactly and truthfully state the actual weight, assay value, and total amount paid for any lot or lots of ore purchased, or who, by any secret understanding or agreement with another, shall issue a bill of sale or certificate of purchase that does not correctly and truthfully set forth the weight assay value, and total amount paid for any lot or lots of ore, purchased by him or them, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be fined in a sum not exceeding $1,000 nor less than $100, or imprisonment not more than one year, or both, at the discretion of the court."—*New Mexico Exchange.*

AN Austrian engineer has discovered a new method of disintegrating rocks. The chief feature of this system is to employ a hollow cylinder like a gas pipe, and to place a dynamite cartridge, not as hitherto, in a hole bored into the rock to be blasted, but into the cylinder in question. The cartridge only touches the surface of the rock which it is desired to shatter. The explosion of the dynamite is effected by means of electricity, and the effect is said to be greater than from the usual cartridge in a hole in the rock. The rock is shattered into fragments so small that a fair stream is able to wash them away without help, whereas in the case of gunpowder the rock is only split up into blocks more or less troublesome to remove.

MECHANICAL PROGRESS.

Water Tubes an Element of Safety.

Some recent actual occurrences have a very suggestive bearing upon the relative degree of immensity from violent and disastrous boiler explosions possessed, respectively, by the water tube and fire tube system of boiler construction. We copy from the *Manufacturer and Builder:*

The first case is that of an accident resulting through gross carelessness to a steam boiler on the water tube system as constructed by Messrs. Babcock & Wilcox. The circumstances of the case were such as to make the test to which the boiler was put a most severe one, and the fact that the result was *not* a disastrous explosion, scores several points in favor of the water tube system. The boiler here referred to is located in the Brooklyn Sugar Refinery, and is rated at 300-horse power, being one of a set of 1500-horse power. Recently, by one of those oversights that now and then cost scores of lives under the same circumstances, the feed water was cut off, and not noticed until the water level became so low that the boiler was nearly empty and the tubes were overheated. Only one of the tubes burst, and this was the extent of the damage, which was speedily repaired at a cost of $15, and the works were running the next day.

The second case is very analagous, but is even more instructive, as the boiler was subjected to a severer ordeal than the other. This boiler is in the Elizabeth (N. J.) jail, and was of the same kind as that in the foregoing case. It was in charge of one of the convicts, who, after starting his fire as usual in the morning, was surprised not to observe, after an hour or so of waiting, any signs of activity in his steam gauge. This fact was disclosed to some of the officials of the prison, and an investigation was instituted to ascertain the cause, disclosing a fact that at once relieved the boiler from any responsibility for the absence of steam—for there was no water in it. It also showed that the blow-cock was wide open, and had been since the night before. What followed, we give in Mr. Watson's own words:

"After the syndicate had opened the furnace door and seen the white hot tubes, it was thought a good idea to get some water in the boiler as quickly as possible; so they shut the blow-cock (for a wonder) and turned on the city water. The result justified their expectations; steam was made very quickly; for a moment it roared through the safety valve with a fearsome sound—and that is all that happened, beyond the renewal of a few of the tubes, and one steel casting."

What might have happened had either of these boilers been fire-tube instead of water-tube boilers we do not pretend to say, but think Mr. Watson is not far out of the way in venturing the statement that "it is not contrary to precedent to say that, in all probability, there would have been an opportunity for a coroner's inquest and a new jail."

A NEW INVENTION IN IRON SMELTING.—We learn that an innovation has been introduced in the Scotch iron smelting trade which may be considered the most important that has been effected since the introduction of the hot-blast process. For some considerable time past experiments on different scales have been made further to utilize the waste gases before burning them, by extracting the tar and ammonia which were found to be present in the gases of all blast-furnaces where coal was used as fuel, and, after much labor and numerous experiments, Messrs. Alexander & M'Cosh, of the firm of William Baird & Co., Gartsherrie, are stated to have successfully solved the problem, in practical form, of extracting the tar and ammonia, as subsidiary products, from their blast-furnaces without increasing the cost of manufacture, or in the slightest degree disturbing the process of smelting. Some time ago a work on a very considerable scale was erected at Gartsherrie iron works, and is now said to be in successful operation, recovering the tar and ammonia from blast-furnace gases, which, after passing through the apparatus and parting with their valuable products, are conveyed by piping to different parts of the works for the generation of steam and other purposes. We hear that so successfully have these operations proved that the Gartsherrie firm are now erecting similar apparatus for all the furnaces at their various works in Lanarkshire and Ayrshire.

INDUSTRIES IN SOUTH CAROLINA.—In nothing is the progress of Charleston, S. C., shown more vividly than in the diversification of industries. There are in and around Charleston to-day 138 factories of different kinds, employing 4,356 persons, with an annual product valued at $8,116,568. This includes the fertilizer companies, 11 in number, who employ 920 hands, and whose products for the year are valued at $2,562,000. The fact may not be generally known that it was in Charleston that the first American-built locomotive turned its wheels for the first time on a railroad track—at the depot of the Charleston & Augusta railroad.

BREAKAGE OF COAL CHISELS.—The usual cause of chisels breaking is from overheating, too high temperature, and by striking the finishing blows on the edge. A chisel should not be finished in dressing it by hammering on the edges.

Individuality of Metals.

The *Ironmonger,* in a recent editorial upon the subject, presents some ideas which will be of interest to our readers:

Within the past few years we have heard a great deal of lamentation from Mr. Ruskin and other gentlemen, whose artistic sympathies and fine perceptions of the indefinitely beautiful are somewhat out of accord with the hard facts of this prosaic age, of the decadence of individuality in workmanship. These critics have bewailed the leveling effect of modern manufacturing competition, and have lost no opportunity of assuring us that machinery has not merely vulgarized everything, but has made our mechanics themselves into human machines. With all kinds of things produced by mechanical means the ancient pride of personal production has been wholly eradicated, we are told, and the artisan, who literally forms a portion of the machinery, cares nothing for the outcome of his daily labor so long as he duly receives its pecuniary value. Admitting that these remarks were largely justified a few years ago, we venture to dispute their equal application at the present time. The dead level of machine-made goods has brought about a reaction—in metal work at all events—which has been aided and fostered by the tastes of the fashionable world for the time being. The revival of Queen Anne and Renaissance patterns has had much influence in this respect, but it is probable that other causes have been working in the same direction.

Certainly there has been more hand-made metal work turned out lately than for a very long series of years before, and that, too, of a higher class than had been seen in England at any former time. We may not possess any modern rivals of the Quintin Matsys, Albrecht Durers or Peter Vischers of mediæval periods, yet we have undoubtedly a number of skilled workers in metals, who possess artistic taste, individuality and technical skill, and who are doing excellent work in a quiet and unostentatious manner.

Any one who is conversant with what is going on in the world must be aware of the substantial accuracy of these statements. In *repousse* work for panels and other purposes, the productions of recent years have contained much that is admirable, while those whose energies have been devoted to church decorations have made great headway. In the very ordinary items of house-furnishing, too, the change has been strongly emphasized. Fenders, grates, fire-dogs, kerbs, fire-irons (or rather brasses) and gasfittings have all been revolutionized by the preference accorded to hand-made work. In a similar degree bedsteads have undergone a similar change. Stamped and pierced details have been replaced by the productions of the forger and chaser, and castings have given way for hammered and chiseled designs. In this manner more costly articles have been made to suit the tastes and pockets of wealthy purchasers, and the middle classes have been educated up to the difference as well as the distinction existing between articles produced by the gross from the same mold or pattern and the separate and distinct products of the individual artisan. In France, Belgium and Germany there has always been more individuality in these respects than with ourselves, and those countries are in some particulars ahead of us in handwork. Whether their workmen possess higher taste or more skill in consequence may be doubted. Here and there their better technical education may give them temporary advantages, but, on the whole, there is no evidence in proof of their superiority. The Belgians may excel in some kinds of candelabra and chandeliers, and the Germans in grills, door-panels and balconies; but their lead is not a long one, and with a continuance of the existing preference for hand-made work in this country our rising men may be trusted to give a good account of themselves in open competition with the whole world.

SILVERING IRON.—A manufacturer in Vienna employs the following process for silvering iron: He first covers the iron with mercury, and silvers by the galvanic process. By heating to 300° C., the mercury evaporates and the silver layer is fixed. Ironware is first heated with diluted hydrochloric acid, and then dipped in a solution of nitrate of mercury, being, at the same time, in communication with the zinc pole of an electric battery, a piece of gas carbon or platinum being used as an anode for the other pole. The metal is soon covered with a layer of quicksilver; is then taken out and well washed and silvered in a silver solution. To save silver the ware can be first covered with a layer of tin; one part of cream of tartar is dissolved in eight parts of boiling water, and one or more tin anodes are joined with the carbon pole of a Bunsen element. The zinc pole communicates with a well-cleaned piece of copper, and the battery is made to act till enough tin has deposited on the copper, when this is taken out and the ironware put in its place. The ware thus covered with tin, chemically pure and silvered, is much cheaper than any other silvered metals.

ASBESTOS AS A FOUNDATION FOR STEAM HAMMERS.—The blacksmith shop of the Pittsburg, Fort Wayne & Chicago railroad, at Pittsburg, has been much troubled by the unsetting of the brick forges by the jar of the steam hammer, and forges of asbestos paper have, it is said, proved a decidedly successful method of overcoming all difficulties.

SCIENTIFIC PROGRESS.

The Solar Constant—Boiling Water by Direct Sunlight.

Professor S. P. Langley has submitted to the Chief Signal Officer an abstract of the results of the Mount Whitney Expedition to determine the amount of heat the sun sends to the earth, in technical terms, the solar constant. Mount Whitney, in southern California, was selected for the observation because it combined the advantages of great elevation, extreme dryness of atmosphere, and abrupt rise from the plain. The party of observation consisted of Captain O. E. Michaelis, United States Army; two non-commissioned officers of the Signal Service, six soldiers acting as an escort, four civilian assistants, and Professor Langley. Systematic work did not commence until the last days of August, 1881. Professor Langley summarizes the results ascertained as follows:

"The approximate estimate of the solar constant is from 2.6 to 3.0 caloric, by which is meant that the direct solar radiation before absorption by the earth's atmosphere would in falling, for one minute, normally upon an area of one square centimeter, raise the temperature of one gramme of water 2.6 or 3.0 centigrade. This implies its ability to melt annually a crust of ice covering the whole earth over 150 ft. thick. This amount is one-half greater than the received value of Poullet, and greater than the latest determinations of Messrs. Crova and Violle."

On the summit of Mount Whitney an ordinary black bulb thermometer *in vacuo* rose to 130 Fahr., while the temperature in a blackened copper vessel, covered by two sheets of common window glass, rose above the boiling point. With such a vessel water could be boiled among the snowfields of Mount Whitney by the direct solar rays.

While the influence of the atmosphere is to shut off from the earth's surface a considerable portion of the sun's heat by absorbing it, the capacity of the air to store heat and prevent its radiation into space serves to make the earth habitable. Otherwise, in Professor Langley's opinion, the surface temperature, even under the tropics, would be lower than the lowest recorded degrees of Arctic cold. Another effect of the selective absorption of the atmosphere is to change the apparent color of the sun. In a transparent atmosphere the now "golden sun" would appear blue.

WARMING HOUSES BY THE SUN'S RAYS.—Prof. E. S. Morse, of the Essex (Mass.) Institute, has devised an ingenious arrangement for utilizing the heat in the sun's rays in warming our houses. His invention consists of a surface of blackened slate under glass, fixed to the sunny side or sides of a house, with vents in the walls so arranged that the cold air of a room is let out at the bottom of the slate and forced in again at the top by the ascending heated column between the slate and the glass. The out-door air can be admitted also if desirable. The thing is so simple, and apparently self-evident, that one only wonders that it has not always been in use. Its entire practicableness is demonstrated in the heating of the Professor's study in his cottage at Salem. The value of the improvement for daily warming buildings like churches and school-houses, which, when allowed to get cold between using, consume immense quantities of heat before they are fairly warmed again, is evident. Of course some other means of heating must be available when the sun does not shine.

ANTIQUITY OF WEAVING.—Archæological researches have shown indisputably that the art of weaving was practiced in prehistoric times. It may even date back nearly to the creation of man, as fragments of woven cloth have been found among the relics of the Lake Dwellers, who are supposed to have been about the first representatives of the human race. The Bronze age furnished specimens which placed the art above most others in degree of perfection, even fabrics of wool being found in the remains of Denmark, Scandinavia and England—the remains of France and Switzerland yielding linen fabrics. The oldest historical reference to the art of weaving is furnished by the Bible. Job lamented that his days were passing with the fleetness of a weaver's shuttle, and Joseph's coat attired in "vestures of fine linen."

A CURIOUS case of electrical generation by friction was recently brought before the German Electro-Technical Union by Dr. Werner Siemens, of Berlin. It was observed in a brewery in that city, and caused considerable alarm among the workmen. The brewery building is constructed of stone and iron, and the floor is laid with asphalt. In the upper story is a malt cleaner, from which the malt passes by an iron chute to the floor below, where it is received in wagons for distribution throughout the works. When the cleaner remained in action for some time the friction of the malt on the iron chute generated electricity, which produced a continuous stream of sparks. The malt itself crackled, and sparks flew from it to the hands of the workmen. When Dr. Siemens was called in to investigate the phenomenon, he showed how the asphalt floor insulated the malt-room from the rest of the building, so that it became a large Leyden jar charged by the electricity generated by the friction of the malt rubbing on the iron chute and on itself.

The Light of the Sky.

Capt. Abney lately read a paper before the British Association on the light of the sky at high altitudes, based upon observations made in the Alps on the Riffel, at a hight of 8,500 ft. His investigations proved that in high altitudes the light of the sky diminishes very much, so as to make photography difficult, and that it is only a tenth or a twentieth of that which is found on the surface of the earth. There was a remarkable absence of the rain-band spectrum. On the Riffel he only saw it once, and that was during a shower. The solar spectrum was the same on the Riffel as in London. He did not believe that aqueous vapor was present in the upper regions; at all events, in the form in which it exists below. In the red part of the spectrum he found that the benzine and alcohol which had been found to exist in the atmosphere actually increased in strength in the higher regions, and he could only suppose that benzine and alcohol are not of terrestrial formation, but come to us from space. Dr. Glaisher said he had never failed up to five miles in getting a deposition of vapor, and there was no part of the earth's atmosphere probably in which there was no aqueous vapor. At a hight of seven miles in a balloon he had seen cirrus clouds still higher, and there was a great difference between the state of the atmosphere in a free balloon and on a mountain side. Prof. S. P. Langley, of Allegheny, Pennsylvania, in a paper on the distribution of energy in the solar spectrum, stated that he had investigated the infra-red spectrum at a hight of 13,000 ft. in a very dry region, and found that it extends very much farther than had been mapped heretofore. The wave lengths of the visible parts of the red end of the spectrum are only one-fourth of those in the infra-spectrum, so that three-fourths of the energy were invisible. His observations proved the existence of great gaps in the spectrum, and he was inclined to support Abney's conclusions on the existence of benzine and alcohol in space.

CURIOUS FACT CONCERNING BOILING WATER.—At a recent Association meeting, Mr. A. J. Haddock, A. I. C., related the following: A kettle filled with boiling water was hung in the hottest room of some Turkish baths with the lid on. The temperature of the surrounding air was 262° Fahr. After about an hour the temperature of the water was taken, and indicated, as was expected, 212°. The kettle was then rehung with the lid off. The temperature of the room was now 252°. In 20 minutes the temperature of the water had fallen to 185°, in 30 minutes to 178°, in 45 minutes to 170°, and was evidently still falling. The manager stated that it generally fell finally to about 140°, when a point of equilibrium seemed to be established, and the water neither got hotter nor cooler. Mr. Haddock supposes this loss of heat was due to rapid vaporization and conversion of the sensible heat of the water into the latent heat of steam, and as dry air is a very bad conductor of heat (one of the worst known), the heat required to convert a portion of the water into steam had to be abstracted from the remainder of the water, thus lowering its temperature. In substantiation of this explanation we know as a fact that if water is placed in a vessel over a large bulk of strong sulphuric acid, in the receiver of an air-pump, and the air is exhausted, the rapid evaporation of one portion of the water will actually cause the rest to freeze.—*Mineral Water Trade Review.*

INFLUENCE OF SNOW ON TEMPERATURE OF THE LOWER STRATA OF AIR.—The influence of snow on the temperature of the lower strata of air has been shown by Mr. Bilwieler from comparison of the last two winters at Zurich, Switzerland. The general conditions of weather were very much the same, long prevailing barometeric maxima with abnormal heating of the upper air and frost in the lower; but whereas in 1879–80 the temperature at Zurich sank to 13° C. early in December and repeatedly reached 9.5° and 10.5°, the extreme colds last winter were only 3.5° and 4.2°. The winters contrasted strongly (especially in December) as regards snowfall in central Europe. The influence of the snow cover consists in its breaking, as a bad conductor, the connection between the ground and the air. In December the ground is considerably warmer than the air, which is thus slowly heated from below if snow is absent, the presence of snow interrupting this transference of heat almost entirely. The surface of the snow cools greatly by radiation, and this cooling is shared directly by the air.

VOLATILIZING METALS IN VACUUM.—It is well known that metals may be volatilized at elevated temperatures, the heat of the electric arc being sometimes used to effect it. M. Demarcay has recently made a series of experiments in which he observed the temperature of volatilization of various metals in a vacuum. These he finds to be comparatively very low, cadmium volatilizing at 160° Fahr., zinc at 184°, antimony and bismuth at 292°, and tin and lead at 360°.

THE presence of magnesia in limestone, even in very small quantities, can be detected, according to Pichard, by its alkaline reaction. If the pulverized stone does not at once react on red litmus paper, he directs that a portion be heated on platinum foil just below dull redness. Pure limestone remains unchanged, but if one-1000th of magnesia is present an alkaline reaction will readily be obtained.

Bullion Shipments.

We quote shipments since our last and ehall he pleased to receive further reports:

Hanauer, Oct. 17th, $3,920; Germania, 17th, $1,350; Germania, 18th, $4.860; Tintic, 18th, $4,170; Horn Silver, 18th, $3,500; Horn Silver, 20th, $26,971; Germania, 20th, $4,500; Stormont, 20th, $4,400; Hanauer, 20th, $4,280; Horn Silver, 21st, $10 000; Bullionville, 21st, $1,590; Horn Silver, 22d, $7,500; Germania, 22d, $4,270; Hanauer, 22d, $2,250. The metal shipments for the week ending Oct. 15, 1882, from Salt Lake, comprised 53 cars of hullion, 1,209,462 pounds, sent East, and two care copper matte, 40,259 pounds, sent to Colorado, making a grand total of 55 care, aggregating 1,249,721 pounds. The receipts of precious metale reported by the banke of Salt Lake for the week ending October 20, 1882, aggregates in value $130,171 87. Navajo, 18th, $19,964. Standard, 16th, $20,153; Christy, 18th, $4,714; Northern Belle, 16th, $15,770; Bodie Tunnel, 20th, $2,864; Northern Belle, 16th, $13,161; Star, 20th, $2,000; Christy, 23d, $4,457; Independence, 23d, $4 000; Navajo, 23d, $16,000; Bodie Cor., 23d, $10.720; Ophir, $9,278; Contention, 21st, $26,379; Bodie Tunnel, 24th, $3,719.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

ASSESSMENTS—STOCKS ON THE LISTS OF THE BOARDS.

Mining Share Market.

Bueiness at the stock hoards is by no means lively just now, though occasionally a spnrt comes that makes matters lively for a day or two. The market is waiting a little strike or so up on the Comstock, hnt none comes. At the north end all is going forward well in the several drifts, the connection of which is to open up some 3,000 ft. of gronnd along the lode to exploration hy means of crosscute, and in a few weeks much activity will be seen in that direction.

About the time this work is completed, they will he ready to explore the Ophir and Mexican, at the depth of 3,100 ft.

Although the Chollar west drift cut no ore, and though many talk of the level as a failure on that account, not a few mining men look upon the gronnd as not prospected at all. They say the drift shows hut a small section of ground and tells nothing of what may lie on either side. They say a crossent might in the same way have been run within 50 ft. of the big honanza without cutting a pound of ore.

At Gold Hill there are hopes of the Crown Point finding a considerable amount of good ore in their ground, as it is said the rich ore now being followed in the Kentuck is pretty sure to extend into Crown Point ground.

Several parties ahont Dayton, Nevada, are mining for tailinge, which were scattered over the flats in the days when Dayton had a dozen qnartz mills. The tailings were covered np with earth and gravel in places two or three feet deep, and hecame covered with sage hrnsh and other hrushes, and in several places were under cultivation. The strata of tailings are found hy sinking shafts and stripping the gravel.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Cooper Medical College—Oct. 25th. Object: The cultivation and advancement of medicine and surgery, and of the sciences cognate thereto. Directors—Levi Cooper Lane, Henry Gibbons, Jr., Richard Henry Plummer, William Ancium Douglass and Edward Robeson Taylor.

S. F. Edison Electric Light Co.—Oct. 27th. Directors—George S. Ladd, Ignatz Steinhart, Edgar Mills, D. Cohen, W. E. Dean, Lewis Gerstle, E. L. G. Steele. Capital stock, $5,000,000, divided in 50 000 shares of a par value of $100 each, and of which $3,500,000 has been subscribed as follows: Ignatz Steinhart, $200,000; W. E. Dean, $200,000; D. Cohne, $200,000; Goodall, Perkins & Co., $200,000; C. Adolph Low & Co., $200,000; Edward L. G. Steele, $50,000; Edgar Mills, $200,000; Lewis Gerstle, $200,000; M. Greenwood, $200,000; Frank McLaughlin, $200,000; A. J. Bryant, $100,000; James G. Eastland, $200,000; W. W. Traylor, $200,000; Eugene F. Dewey, $200,000; A. McKinley, $100.000; Frank Jaynes, $100,000; Gordon Blanding, $100,000; George S. Ladd, $050,000. It is the intention of the company to establish a large lighting district in this city as soon as the machinery and other materials can he manufactured. The district will he operated from one large station, centrally located, and the electricity will be generated hy 12 large steam dynamos, weighing 62,000 lbs. each. The engines will work independently of each other, hut will feed their currents of electricity into one common set of main conductors. Nine dynamos will supply all the electricity required for all the lamps, and three will be kept in reserve. Steam will be furnished by eight 250-horse power boilers, two of which will he in reserve. These engines and hoilers in reserve will effectually prevent any interruption of service hy reason of disahled machinery. The electricity will be carried under the streets and into huildings hy large copper conductors insulated in iron pipes, and there will he no overground or overhead wires. A simple meter placed in each huilding will show, in thousands of feet, the exact amount of electricity used by each consumer, and he will pay only for what he uses, and at the same price as for gas, or perhaps lower.

News in Brief.

Maud S. is to he shipped to Cincinnati in December.

In Septemher Michigan farmere marketed 12,740,000 hnshels of wheat.

A collision of freight trains at Rhine Cliff, N. Y., caused a loss of $80,000.

Baker Pasha has been officially appointed to the command of the new Egyptian army.

The value of supplies issued to the Indians hy the government during the year was $37,196.

The price of Russian grain has greatly declined, owing to the competition from America.

Two hod-carriers fought on the top of a three-story building at New York Saturday, and fell to the ground, hoth heing killed.

The new Northern Pacifio Railroad hridge over the Missouri river at Bismarck, D. T., was formally opened to traffic Saturday.

The new Minister from Japan arrived at Washington Saturday evening, in 22 days and 9 honrs from Yokahama—the quickest time on record.

The government's receipts for the capitation tax on immigrants, under the Act of August 3 1, np to and inclnding September 30th, amounted to $37,660.

Dr. Boynton's claim for servicee during President Garfield's illnees is for $4,500, heing $5,500 less than any claim for profeesional eervices yet received.

The will of Jeannette Buchanan Goelet has heen filed for probate in New York. After disposing of a large amount of real estate, she bequeathes to her relatives over $700,000.

It is said that Sntro & Co. have purchased a controlling interest in the Omnihus railroad, in this city, and that the cars of the line will hereafter he run hy electrical motors. It is claimed they will work a saving of $6,000 a month.

Purses of $10,000 a year or a lnmp sum of $250,000 each were offered to Sir Garnet Wolseley and Sir Beanchamp Seymour. They chose the latter, which indicatee that the available rate of intereet ie not bad, and that life insurance in its practical aspect is understood hy the War Office.

Messrs. Paxton & Curtis, of Enreka, Nev., with ex-Gnv. Low, have hought about 7,000 acres on Eel river, Humholdt county, known as the Ralston tract. The price paid is reported at $100,000. This syndicate proposes to hnild a railway from the track to tide water at Humholdt hay, a distance of eome 20 miles. Prominent lumher men of Chicago and Detroit have had representatives here at various times during the past year, with a view of ultimately using redwood for finishing work in place of white pine.

A honee was hurning at Oshkosh, Wis., and a woman was left inside. Her hushand cried: "Five thousand dollars to the man who saves her!" A fireman dashed in at great personal risk, and hrought her out alivc. Although the huehand is very wealthy, he refused to give a dollar of the reward; hut the Snpreme Court decides that the offer of $5 000 was valid, and that the money must he paid.

Acting Secretary of the Treasury French decides that a Chinaman, having a through ticket from New York to any place in the United States, having passed through Canada on the Grand Trunk Railway, is entitled to admission into the United States without further evidence of his right than a ticket.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

CALAVERAS.

Silver.—*Mountain Echo*, Oct. 20: Recent assays from the Jones mine proves it to be one of the richest silver mines on this coast. If anyhedy doubts it let them read the following and be convinced: An assay was recently made from one ton of ore from the Jones mine, which yielded $760 in silver and $360 in gold; total, $1,120. This we think is enough to convince the most skeptical. The mine is improving all the time At a depth nf 50 ft the vein is 11 ft in width, and will average from $40 to $50 per ton. The shaft is now being sunk deeper.

Lindsay & Co. are getting everything in ship-shape in their mine. The tunnel is nearly completed, and they will soon begin to realize something for their labor. While at the mine the other day we were shown some exceedingly rich specimens of ore.

MARIPOSA.

Morning Star Mine.—Mariposa *Gazette*, Oct. 20: This mine, situated at the head of Sebastapol gulch, nn the south side of the Merced river, about 4 miles by trail from Bear valley, formerly belonging to Mr. Phil. Gossar, now bonded to a company of capitalists, started up its new 10-stamp mill on Monday last. This mioe will undoubtedly hecome a valuahle property, as it is already developed sufficiently to guarantee its success. Uncle Phil says in less than 48 hours the plates were covered with gold, and he is highly elated at the prospect of success.

NEVADA.

Some of the Quartz Claims.—Nevada *Transcript*, Oct 20: The mill building at the Mt. Auburn mine will be completed this week, and the machiury will soon he ready to start.....The Nevada City mine is having 10 more stamps put into its mill, making 20 in all. Lawrence & Barlow are the contractors.....The Murchie Co. proposes to have its present complement of 10 stamps increased to 20 or 30 early next spring. The mine is looking well.....Steam has been started up again at the Pittsburg mine.....The miners at the Sherman Con. tapped an old drain tunnel Thursday night and were driven out by the water. The pump had sufficient capacity to soon master the situation, and now everything is going on again as usual. The incline is being sunk for another level.....A Pelton wheel has been put in to drive the machinery at the Mitchell & Martin mine, and the mill started up again yesterday. There is about 50 tons of ore on the dump, and more being taken out regularly.....An additional boiler is to be put in place at the Charounat mine, and over it a changing room will be built.

PLACER.

Sale of a Good Mine.—Placer *Herald*, Oct. 21: Our townsmen, Messrs. Craig & Fulweiler, have sold their mine to Mr. P. C. Dubois, who is trustee for Eastern parties, for $40,000. It is understood that English capital is interested. The mine is about one mile west of Ophir, and is known by the name of Ophir & Gold Blossom claim. Messrs. Craig & Fulweiler have owned this mine since August, 1880, during which time they have sunk a shaft 86 ft deep, run about 200 ft of levels and taken out about 700 tons nf quartz They have crushed about 400 tons, which has yielded from $8 to $15 per ton free gold, nut including sulphurets. The ledge averages about 2½ ft wide of good rock—the sulphurets assaying from $150 to $2.000 per ton. Messrs. Craig & Fulweiler still retain possession of over 1,000 ft of au eastern extension of the same mine.

Rich Mine.—On last Monday morning Messrs. Peardon & Hawkins, the owners of what is known as the old Shipley mine, which is located near Doty's ravine, about 6 miles from Auhurn, brought into the banking office of Hollenbeck & Andrews 37½ ounces of gold, which was the result of 27 days' run with a 5-stamp mill. This mine has been worked for some time and has been a paying mine from the start.

A Promised Enterprise.—Mr. J. J. O'Sullivan called on us last Tuesday in company with Mr. F. A. Huntington, of San Francisco, and from the former we learn that he has completed all the preliminary arrangements for putting up a large mill on what is known as the Big Ledge, on Rich flat, a short distance south of Auburn. Mr. Huntington is a machinist and mill man, and was here to select the site for the mill and take the measurements for pipe and other needed material. Mr. O'Sullivan left that evening for the East to complete the details of organization of the company, and expects to be back in a few weeks and commence at once the erection of the mill, and the further development nf the mine. This ledge is 8 or 10 ft thick, and, as far as tested, pays, in free gold, exclusive of the sulphurets, hetween $6 and $7 a ton. With extensive facilities for working and milling, there is no apparent reason why it may not prove a paying property.

The Hidden Treasure.—At the famous Hidden Treasure mine, at Sunny South, the enterprising owners are making improvements which, when completed, will enable the company to work their mine much more conveniently and cheaply. They are constructing a very fine, large new dump at the mouth of the upper tunnel. They are enlarging and straightening this tunnel with the intention of using it for the working tunnel, and running their dirt out through it hereafter instead of dumping it down chutes and running it out of the lower tunnel, as at present. This upper tunnel they are preparing to lay with T rails, and they are building a large lot of new cars, designed for use on the new track. At present a mule is used for hauling the cars in and out of the mine, but this power they expect to supplant with a compressed air engine.

PLUMAS.

Cherokee Mine.—Greenville *Bulletin*, Oct. 20: Last week the 8-inch lift pump was changed for an 8-inch pole plunger; this pump throws water to the surface from a large tank at the 200 level. A 6-inch lift pump throws water from the bottom of the shaft to that station. The shaft is now down about 36 ft below the 200 level. When making the change in the pumping machinery a delay in getting out ore caused a stoppage at the mill of three days' duration. On the 15th the mill was started up again, with 15 stamps running. At the Greenville Iron Works a Pelton wheel is being made for the mill, which will give power enough to run all the stamps at the lowest stage of water.

The Reservoir.—The approach of winter finds us in vastly better condition than at the corresponding season last year; then the water in the reservoir was nearly exhausted, and, in fact, soon after this time it was all used up. Now there is an abundance; this was assured by the increased capacity of the reservoir, made last winter and spring. The recent heavy rains have added largely to the amount of water in the lake, and made assurance doubly sure that every mill can be fully supplied with water.

Crescent.—At the Crescent mine a force of 20 men are at work. The old shaft will he put in thorough repair and a drift run from that to the new shaft lately put down by Mr. Davis. From the ledge lately discovered by him ore is being taken out rapidly, and is richer than when first struck. The parties interested are very confident it will mill over $20 per ton. Teams are hauling lumber as fast as possible, and the mill and hoisting works will soon ho in complete working order.

Antelope.—The owners of the Antelope mine, in Long valley, are about to put in pans in addition to their mill, and work the ore in the same manner as the silver ores of the Comstock were worked, though the Antelope ore is gold hearing.

SIERRA.

Water.—*Mountain Messenger*, Oct. 21: The American Hill hydraulic claim has been put in good working order

for more thorough development next spring. Supt. J. Burman came down Wednesday and said that the recent rainfall had given him considerable water for washing.

FOREST CITY.—Sierra *Tribune*, Oct. 21: The Bald Mountain Co. is getting good pay out of Lowell Avenue, and the indications are that they have a channel running parallel with the other one the full length of the claim. They intend starting off-side gangways soon. Owing to the late rain the company is unable to pipe no both dams.

THE Ruby Co. is pushing work ahead in its mine as fast as possible. They have started to raise an incline, which, as soon as completed, will do away with the shafts and permit the working of gravel at less expense. The company at present is employing about 10 men, but, as soon as the claim is sufficiently opened, a much larger force will be put at work.

THE Bald Mountain Extension Co. is still pushing its tunnel ahead as rapidly as possible for three shifts. In the last upraise gravel was found which prospects well, but not in paying quantities. The indications are that they are not in the center of the channel. The tunnel is now in about 125 ft from the last raise, and it is expected to raise again soon, when it is likely that gravel will be struck in paying quantities.

THE usual shipment of $10,750 was made from the Rainbow mine this week. But little rock remains on the dump, most of it having been crushed; and, as the tunnel will soon tap the ledge, the company will be able to discard the use of the hoisting works and work the ledge through the tunnel at a far less expense. The cable on the tramway broke, and the company is now waiting for a man to come up from San Francisco and splice it, when the mill will be started up again.

TRINITY.

DEADWOOD AND FRENCH GULCH. Trinity *Journal*, Oct. 21: At the Brunswick mine camp we proceeded to the mine, where we found a tunnel nearly 300 ft long, and a shaft about 50 ft deep. The ledge has not been tapped by the tunnel, but is liable to be within a very short distance. In the shaft the ledge is from 2½ to 3 ft in width, and much of the rock shows free gold. Parties conversant with quartz mining affirm say the Brunswick Co. has a splendid prospect, and the property should soon be a dividend-paying one. From the mine we went to French Gulch, where we stopped over night. The town looks a little dilapidated, but the residents are hopeful of much better times in the near future. The Niagara, Washington and other mines are now taking out good rock, and indications favor a quartz boom of no small dimensions. Monday morning we left the gulch for home, coming by way of Lambert's mill and mine on Deadwood. This is one of the most complete, thorough and economical mining and milling operations in the country, and is being run at a large profit.

MINERS generally throughout the county are now ready for water, and put in all their spare time praying for a wet winter.

TUOLUMNE.

IMPORTANT TRANSFERS.—Although the mining boom is over for the present in the most important marts, Tuolumne county has been favored during the time with several important transfers. Some have already built mills and started up, and others are making active preparations to do so. Within the coming winter and spring several valuable mining properties will be opened and in good working order.

ABOUT two months ago Mr. Divoll took out a "small dab" of $25,000 from his Bonanza mine on Piety Hill. Not much of anything has been done since, except to keep the mine clear from water, which comes in in great abundance—the shaft being below the creek level, which possibly makes some difference as regards the supply. Divoll is expected in town in a few days to inspect the property.

THE Sonora foundry has cast a mortar weighing 1,600 lbs, to run 5 stamps, for the Buchanan mining company. It is the intention of Supt. Moore to equip the new mill with all the modern appliances of mining machinery, and he has wisely concluded to employ our foundry-men to do the work. We are pleased to see some of the gold taken from our mines left in circulation for the benefit of its citizens.

NEVADA.

WASHOE DISTRICT.

CON. VIRGINIA.—On the 2700 level the joint California east drift is being advanced at the rate of about 25 ft per week.

BELCHER.—A considerable amount of low-grade ore is being extracted from the old upper levels at several points.

CROWN POINT.—About the usual amount of ore is being extracted from points on the lower levels and sent to mills on the Carson river.

SIERRA NEVADA.—Good progress is making in the north and south drifts on the 2700 level, and they will now shortly be connected.

UTAH.—The Incline is now being repaired and timbered at a point a little above 1750 level. While these repairs are in progress no work can be done in the drifts below.

GOULD & CURRY.—The southwest drift on the 2500 level is making good headway. The diamond drill was run ahead about 170 ft, and no water found that will interfere with progress in that direction. The rock ahead is quite hard.

SCORPION.—No change of material worthy of note has been observed in the crosscut. It is doubtless still a great distance to the east wall. Against this wall lies a black slate formation which comes to the surface, where it has an eastern dip.

MEXICAN.—The tank station at the 3000 level of the joint Ophir winze has been completed and sinking has been resumed. The northwest drift on the 2900 level is making good progress toward the drift that is coming south in the Union Con. on the same level.

UNION CON.—Good progress is making in the east crosscut on the 2500 level. The material is porphyry, clay and streaks of quartz. On the 2700 level No. 3 crosscut is making over 20 ft per week. It is run from the main lateral drift. South drift No. 2 on this level is also making good progress.

AURORA DISTRICT.

HOPEFUL OUTLOOK.—Esmoralda *Herald*, Oct. 21: The outlook for this much-abused mining district is ripe with the assurance of success, and all that is needed to substantiate ourselves is "a long pull, a strong pull, and a pull altogether." "There's millions in it."

CORTEZ.—In this mine the ledge in the lowest level looks stronger than anywhere else in the mine, and gives positive promise of a bonanza in the fullest sense of the word. The ledge carries ore assaying $30 per ton—$27 in silver and $3 in gold. All that the company has to do now is to prosecute the work of exploration and prove that a true fissure vein extends through this district, and that they are the first ones to strike it.

THE Silver Lining has developed into a profitable property. The ore is fine in quality, and when the mill tunes up the company can go to work in earnest and secure the "dollars of our dads."

THE Lewis Con. is improving in its ore in quality and quantity. The usual force are pushing developments.

PROSPECTORS AT WORK.—The pop of the giant powder is heard on the hills. The owners of claims are doing assessment work. The old proverb says: "He becometh poor that dealeth with a slack hand; but the hand of the diligent maketh rich."

DEL MONTE PROPERTY LEASED.—Mr. W. P. McIntosh has secured a lease of the entire Del Monte properties, and will begin soon to prospect. Some of the old dumps will pay well in many instances, as the coasters of yore simply skimmed the surface. Ore paying from $15 to $100 per ton can be easily picked out of old dumps once sorted, and, unless all signs fail, the gentleman has a good thing.

EUREKA DISTRICT.

SILVER LICK.—Eureka *Sentinel*, Oct. 21: There are 6 men at work on the Silver Lick series of mines on Adams Hill. The main shaft is down 90 ft from the surface, from which point there is a short drift in good ore, of which there has been several tons hoisted to the surface. The Silver Lick is a regular producer, the ore being generally of high grade.

ADOLPH SCHNABEL is at work with 5 men in the Hercules mine on Adams' Hill. There are 75 tons of high grade ore on the dump, principally quartz. This is the result of 6 weeks' work. Drifting has been commenced from the shaft, which is 45 feet deep, the bottom being all in ore. This mine adjoins the Silver Lick, and bids fair to become a very valuable property.

A VALUABLE DISCOVERY.—While grading for a road near the Albion hoisting works yesterday, about 25 ft up the hill east from the old Uncle Sam shaft, a body of galena ore was uncovered about 18 in. below the surface. Four men were put to work at once to see what was struck. They opened out the body 10 ft square, and in ore, about the middle of which they put a blast that made a hole about 4 ft. square and 3 ft deep, all in solid ore. The extent of the deposit can only be conjectured, but, from its location it is judged to be connected with, and to form a part of, the mineral below in the mine below. A shaft will be sunk on it immediately. The ore is fine-looking galena, and is estimated to go from $70 to $100 per ton.

LEWIS DISTRICT.

TRIBUTERS.—Lewis *Herald*, Oct. 18: The tributers on the Eagle, who have been working about 15 days, have their stops opened up in good shape and about 4 tons of ore on the dump; the ledge is looking first-rate.

CHLORIDE.—About 20 tons of ore have been taken out of the Chloride mine by the leasers. A pack train started Monday to get the ore down, and it will be milled at the Highland Chief mill right away.

THE Starr-Grove mining property has been redeemed by Mr. G. W. Bothwell, and it is expected that operations will be resumed in a short time.

MORNING STAR MINE.—The incline shaft on the Morning Star mine is being sunk at a fair rate, and the ledge is looking well; the north drift is being driven ahead in good ore, the ledge still holding its own. A new ore dump is being graded, and everything around the mine is in first-class working order.

OSCEOLA DISTRICT.

GOLD.—Ploche *Record*, Oct. 14: Among some specimens of gold rock that Postmaster G. Odell brought from the rich find in Osceola, was a piece weighing a pound and from which Mr. P. Vallejo extracted, per assay, the sum of $1.22. As a result of the high percentage attained in making concentrations the furnace is turning out 20 bars of bullion more per 24 hours than it has at any one time since the last of August. Mr. Gentry, from Beaver county, Utah, has taken the tailings contract from off the hands of the Nilson Bros. The contract calls for the delivery of all the tailings which the company may require to keep the concentrating tables running, which average about 150 tons per 24 hours. As the distance is only a few hundred yards from the tailings pit to the furnace, those who work at the business must be expert shovelmen, but to such there is money in the business. Messrs. Gilmer & Salisbury recently made an examination of the ferror mine. An average sample of the entire bottom of the upper shaft, taken by and assayed for them, went $90 in silver and 70 per cent. lead.

SILVER GLANCE DISTRICT.

IMPROVING.—Reno *Gazette*, Oct. 20: Silver Glance district is fast improving its prospects, and promises to become one of the leading mining sections of Nevada, there being little doubt that a lively mining camp will spring up there within a few months. It has many advantages to recommend it. The ore is absolutely free milling, and the veins are large enough to make it an object for capitalists to work them on a considerable scale. But little snow falls there, and operations may be carried on the whole year with but little interruption from inclement weather, such as retards the development of several good mining camps further south. Sweetwater, 35 miles to the south, bids fair to be the leading mining district next year. An experienced miner and capitalist just in from there informs a *Gazette* reporter that there is more promise in Sweetwater than in any district he knows of, and he believes that thriving towns will grow up there and in Silver Glance. Both districts make regular shipments of bullion, and, considering the milling facilities at present employed, the amounts are quite large.

WHITE PINE DISTRICT.

THE TRENCH MINE.—Eureka *Sentinel*, Oct. 20: We learn from John McGrath, who is here at present in the interest of the Trench mining company, that steps are being taken to resume work on the old Treoch mine, and others belonging to the company on White Pine mountain, near Hamilton. Some 7 or 8 tons of ore from these mines will be brought over to the Geddes & Bertrand reduction works to determine whether they can be reduced by the leaching process in use there. If so, leaching vats will be put up at the old Monte Cristo mill, and work be started directly. That the ores can be so reduced is confidently expected. We are told by Mr. McGrath that in addition to the high grade on hand in the mines there is a very large quantity of low grade ore, ranging from $30 to $40 per ton, already mined and ready to be reduced. The resumption of work on White Pine mountain is important, and is another indication that that district may yet regain its lost prestige.

ARIZONA.

WEAVER MINING DISTRICT.—*Miner*, Oct. 20: The exceeding richness of the Marcus mine, in Weaver district, is attracting much attention. This mine is becoming famous because of its rich gold sulphurets. It is a true fissure vein, about 4 ft wide, and in the bottom of the 60-ft winze the sulphuret ore assays $4,000 per ton. The mine is looking fine. The Messrs. Bates Bros. are preparing to concentrate the sulphurets on the ground. Heretofore the crude ore has been shipped to Jersey City for reduction, which has resulted in considerable loss to the owners. At present there is from $25,000 to $30,000 worth of ore sacked at the mine ready for shipment. We hear that an offer of $30,000 for one-fourth of the mine has been refused. Secretary Van Arman has the adjoining claim, upon which he has recently put a force of men at work, and fine results are anticipated, the outcropping assaying from $20 to $50 per ton, and the vein is from 4 to 20 ft in thickness.

BIG BEN.—Cor. Arizona *Miner*, Oct. 20: Business of a mining nature is very quiet at present, very little being done in the way of prospecting. Most of the labor at present is expended in doing assessment work, and from all claims being worked I hear very flattering news. From Copper Mountain, on the Agua Frio, the best of reports are constantly seat forth. Work is being pushed forward at 5 different points, and fine carbonate and oxide ores taken from the tunnel and different shafts. Mr. Stoddard shipped a carload of ore to New York that is calculated to help show the people of the East that the northern part of Arizona has an abundance of ores that it is impossible to excel, notwithstanding the reports set current by the people of the southern part of the Territory that we "are too far north." Twenty men are now being worked at Copper Mountain under the able management of Mr. Harpell, foreman, and more will be employed as soon as they can be worked to advantage.

OLA DOMINION.—Pinal *Drill*, Oct. 21: This company has recently acquired, by purchase, all the property of the old Globe Copper company, and, as now constituted, owns 25 copper mines and 3 furnaces, and will soon be the leading company in the production of copper in Arizona, if not in the United States. We learn from a party who has recently been at Globe, that the company will have employment this winter for 150 men. The old Globe mine is an immense fissure, all the developments showing large bodies of ore. There is now on the dumps and in the stope, 80 ft above the tunnel, at least 6,000 tons of ore, which will average 20%, and in the Old Dominion and Keystone mines there is enough ore in sight to keep one furnace running steadily for 6 months or more. The Black Copper group, comprising 9 mines, will soon be producing ore, as a force of men will, in a few weeks, be at work to develop these valuable mines. The company, in a run of 85 days, produced 645 tons of copper bullion. In a month or two the product will not be less than 500 tons of copper a month.

CASA GRANDE DISTRICT.—Pinal *Drill*, Oct. 21: The mines of this district, which contains about 150 square miles, are situated at a distance of from 12 to 30 miles south of Casa Grande station, in a range of mountains, plainly visible from that place, across the intervening level plain. There is wood in abundance and water can be had at a depth of 20 to 30 ft. The country is perfectly level down to the railroad, and a wagon can be driven right up to the dumps of most of the mines. The country rock is porphyry, quartz and limestone.

VEKOL.—The best-known mine, and the one which first brought the district into prominence, is the Vekol, situated about 31 miles south of the railroad. Owners, Brady & Walker. This mine has shipped about $10,000, up to date.

REWARD.—The Reward was sold this year by the Chilsou Bros., to Eastern parties, for a large sum. There is some talk of putting up a smelter on this mine.

JACK RABBIT.—The Jack Rabbit, owners John Sullivan, Albert Robard and Dick Nicholson, is about 20 miles south of Casa Grande. No walls have yet been found to the ledge, but there is a pay streak 2 ft in width, from which 8 to 10 tons of ore have been shipped, that went from $1,000 to $1,500 per ton. There are 2 shafts, one 50 and the other 65 ft. We have a sample of ore from this mine which is thoroughly impregnated with malleable silver.

GRIZADA.—On the Grizada, owned by John Kron, are several shafts, all in ore—chlorides and black sulphurets—which is being shipped, and yields from $400 to $600 per ton.

WHITE FLAG.—The White Flag is a large, well-defined ledge of carbonate and galena ore, owned by Wilson & Blomberg. There is a 20-ft shaft, all in ore. The same ledge can be traced for miles.

MINERAL WORLD.—The Mineral World is a big blow out; carrying gold and silver, owned by Jerry Fryer, who will shortly start work thereon.

WESTERN UNION.—The Western Union is a similar vein, which crops up from 10 to 40 ft wide for the whole length of the claim.

SILVER BELLE.—On the Silver Belle, owned by Fryer, Crocker, Lewis and Fred. Adams, is a 60 ft shaft, on a 9-ft ledge, very rich in carbonates and malleable silver. Ore has been shipped from this mine, and an offer of $25,000 has been refused therefor.

THE North Star and Long Star are on the same ledge, about 10 miles from Casa Grande. The ledge, which is from 7 to 10 ft wide, is opened up for the whole length of the claim. It assays from $25 to $30 in silver on the surface. E. H. Cage and Albert Robard are the owners.

IDAHO.

THE PHILADELPHIA COMPANY'S BULLION.—Wood River *Times*, Oct. 18: Bullion is now coming down to this city daily from the Philadelphia mining and smelting company's works at Ketchum. During the past 2 days 209 bars have been received and sacked up. These bars weigh an average of 100 lbs., and are to be forwarded to the railroad from this city, thence to Philadelphia, where the Philadelphia mining and smelting company is bound by contract to deliver 1,000 tons of bullion by the 15th of December, 1882. Several teams have already been secured to move this bullion from this city, and it will be endeavored to secure all the freight teams that come in to this city, to move the bullion.

THE OPHIR GROUP SOLD.—The sale of the Ophir group of mines, located near the head of Quigley gulch, 5 miles east of Hailey, has been effected, and the money will be paid on the 20th inst. The owners were George Parsons, W. H. Altaffer and William Seamands. The property was negotiated by Welsey Calbick and sold to a Chicago company. It includes 4 locations, all of which show high-grade galena. Wagons can be taken directly to the mines, over a natural grade, while wood and water are abundant on the locations. The Ophir group is regarded as valuable property, and will be fully developed next summer by the Chicago company.

ANOTHER STRIKE NEAR GALENA.—A new strike of rich silver ore has just been made in the Accident mine, located in White Cloud gulch, near Galena. Col. Brodhead brought the news yesterday and states the strike to be an important one. This ledge was discovered in 1879 by Bill Seamands, and it was while having the representing work done for this year that the rich ore was found. There is now one streak a foot wide, all solid ore, which averages 180 ozs. in silver per ton. Considerable ore is now being extracted, and will be taken out as long as work can be continued.

NARROW-GAUGE MINES.—Supt. Asa W. Clarke states that when John V. Farwell, of Chicago, comes to Hailey next spring, as he intends, a narrow-gauge railway will be built from the Narrow-Gauge mines down to Hailpon which all the ore from the Deer Creek mines will be carried to the terminus of the railroad at Hailey for shipment East, and all mine supplies taken to the mines. The loaded ore cars will be run down with brakes and brought back by mules, as now done in Bingham canyon, Utah, and in Mariposa county, Cal. If this road works well, similar roads will be constructed to other points.

BANNER.—*World*, Oct. 18: Joe Robbins and Ralph Goodliffe came down from Banner the other day for supplies. Mr. Robbins, who is an experienced miner, gives it as his opin on that the Banner makes a better showing than any mine in Idaho with the same extent of development. The pay chute is known to be 300 ft in length, having been run on 100 ft west of the shaft that they have been raising from the lower tunnel to connect with, and 200 ft east. The shaft was sunk to the depth of 100 ft from the tuanel that was run on the pay chute, commencing 100 ft below the surface. Last year drifts were run each way from the bottom of the shaft, the east drift being driven 22 ft, and the west 20 ft, both through high-grade ore. Only 2 or 3 men will work in the mine the coming winter. They will run chutes and put the mine in shape for stoping next spring. The pay seams in the lower tunnel will aggregate about 2 ft, and the ore will mill between $500 and $600 to the ton.

MONTANA.

PONY AND SILVER STAR. *Inter-Mountain*, Oct. 19: Mr. R. B. Wallace, who has just returned from a trip to Pony, gives a most encouraging account of mining operations in that vicinity, and expresses the confident belief that the Pony, Silver Star and Iron Rod mines will be found permanent, productive and profitable in the extreme. Henry Elling, of Virginia, owns 3 very valuable gold properties, one showing 4 ft of $50-ore, another 8 ft of $22-ore, and the third 50 ft of $5 and $6 ore. They are all in process of development, and Mr. Elling is now taking active measures to treat their product. On the Elephant claim, which shows a mass of low-grade ore 50 ft wide, and which, being perfectly free, can be worked with good results, Mr. Elling is now erecting a 20-stamp mill. It is being built of stone and bids fair to be as permanent as the mine, which seems almost inexhaustible.....The difficulty of successfully operating the Broadway mill, owing to a change in the character of the ore in the lower level of the mine, will no longer retard energetic work, as it is proposed to introduce a new process of reduction, the success of which there is little reason to doubt. The Broadway mine is said to be in fine shape to insure a constant and heavy production, the only drawback being that the deep ore, while fully as rich and for the most part richer than that of the upper levels, became too base for successful treatment by the old process.

MOULTON.—Operations in the Moulton mine and mill proceed uninterruptedly, and the outlook for the company is one of assured prosperity. In the east drifts of the mine, above the 300 level, the bulk of the ore has been stoped, but in the west workings the drifts are being extended on good ore, and the stopes all the way to the surface are yielding well. The west drifts are being driven with the view of an early connection with the air shaft, in which the recent developments have been of such a satisfactory nature and so encouraging to the holders of stock. For the first time since the company was organized, it may now be safely stated that the opening of the mine has progressed so far that there is an absolute certainty of keeping the mill supplied with pay ore. The Moulton is now more than self-sustaining, and it is believed that the profits will continue to increase. With a good mine and mill under efficient direction, a continuous output of ore with 1,000 tons as an extracted reserve and backed by the confidence of the stockholders, there is no reason why the Moulton should not realize every reasonable expectation of its owners.

BUTTE *Miner*, Oct. 18: Unusual activity prevailed at all the mines during the past week, the near approach of winter having necessitated quick work in getting in supplies of wood, coal, timber, etc.....At the Alice everything was running smoothly; a full force at work, ore house full and the mills dropping 80 stamps during the entire week.....The Magna Charta continues to hoist its regular 30 tons per day of good paying ore.....The M. C. and V. are still sinking on the shaft, and are 165 ft down. A level will not be driven until a depth of about 265 ft is reached, when a drive will be made to connect with the 200 level of the Magna Charta.....At the Moulton connection was made last Monday between the air shaft and the upraise from the 300 level. A fine body of ore, assaying from $40 to $60, has been uncovered in the east drift from the air shaft. The mill has been running steadily and the ore house is full. We were informed that it became necessary to stop hoisting one day during the past week, because there was no more storage room in the ore house.....The Belle of Butte is working a full force and hoisting ore from the 210 level. Still sinking on the shaft with night and day shifts. At 30 ft below the 210 level a 2-ft vein was pierced, carrying strong native silver and some remarkably fine specimens of wire were taken out. The vein is not yet fully explored, but it is believed to be the most important discovery yet made in the mine.....The Clear Grit is cutting both ways on the 217 level and driving on the east drift, which shows a 5-ft face of good pay. Crosscutting on the west drift through a 12-ft ledge of low grade.....The Lexington was running as usual with a full force, and the mill dropping its 50 stamps every day in the week.

NEW MEXICO.

CERRILLOS.—Cor. New Mexico *Mining World*, Oct. 18: The smelter is running, and we are at last shipping bullion. One week ago to-day she started up, shipping one carload Friday and another one is ready to ship now. She is running like clock work, and the good it is doing is apparent everywhere. The merchants are feeling jubilant and the miners are going to work with more vigor and in brighter spirits than ever before.....Mr. Holman, the owner of the Cash Entry mine, delivered to the smelting company here, 20 tons of ore for $12,500.....The Bonanza mine is shipping ore to the smelter.....The Bonanza No. 3 has resumed work.....The Grand Central tunnel company is pushing ahead steadily. They will soon have machinery on the ground.....The Star, owned by Ainsworth & McClosky, is a fine piece of property. The shaft is sunk to a depth of 120 ft, about 10 ft below water, where crosscuts and levels are run, showing a very fine lead with high-grade ore in good qualities.

NOTES.—*New Southwest*, Oct. 18: The King mine, at Eureka, has about $8,000 worth of ore on the dump.....Diamond drills have been bought by the Santa Rita company for use in their mine.....The Hornet company, of Eureka, is erecting hoisting works on its property.....A large force of men is being worked on the San Jose mine, and the property is looking finely.....The ore from Bremen's Seventy-six mine, that is now being worked at the mill, averages over 100 ozs. in silver to the ton.....The mines at Santa Rita that have been shut down of late with improvements were being made on the surface, will all start up soon.....Messrs. Pope & Smith are working extensively on their claims at Bullaru's peak. A shaft is being sunk on the Oriental, the shaft on the Queen deepened, and cuts have been dug on the Horn Silver and other claims owned by them.....This new strike in the Burros, by William Eckles and Lathian Bros., is attracting considerable attention. The claims now owned by them, consisting of the Wasp, Golden Rule, Grey Eagle and Annie in one group, with the Toughnut and Lucky Cuss adjoining on the east, show a rich float and lead similar to claims in the vicinity of the Blue Bell. The last discovery, made a few days since, is a white quartz containing ruby silver and assaying from 150 ozs. upwards. Their camp is situated about 18 miles west of Silver City, within about one-half mile of the road known as the Ola cut-off, and close to the water known as Mineral spring. A large amount of supplies were shipped to this place the past week, and vigorous prospecting work is being carried on.

OREGON.

BRIEFS.—Jacksonville *Times*, Oct. 20: A. W. Sturgis is still drifting on Forest creek and doing better than ever.....The recent rains have accelerated the miners speed in getting ready for winter.....Welch & Co.'s quartz mill, recently set up in Blackwell district, is about ready to run.....The miners anticipate a good run next season and are making extensive preparations for it.....Ginter & Burckholter, of Applegate, are putting in a long flume, which will greatly facilitate operations.....Wm. Cameron, of Uniontown, informs us that Gin Lin has both his pipes at work with a full head of water.....Hays & Magruder are making preparations at their diggings, on Rogue river, for more extensive mining than ever.....The Sterling company is engaged in fixing its ditch for next season's run. They have about finished cleaning bedrock.....The ground is well soaked and it will not take much more rainy weather to furnish the miners with an abundance of water.....Mulkey & Co. are now making extensive preparations for mining on the Root place, on Wagner creek, where good prospects have been found.....De Lamatter & Co., who own rich diggings on Cow flat, a few miles from Kerbyville, have nearly completed the extension and enlargement of their ditch, which will enable them to reach better ground than ever.....R. W. Herndon came over from Horsehead, Josephine county, this week, and seems well pleased with the prospects. A fine quality of quartz has been struck, but it is not known as yet how extensive the vein is.....R. Cook came over from Steamboat this week, where he is engaged in running a tunnel to strike the ledge that created such an excitement in early days, but suddenly pinched out. He has progressed a distance of 212 ft.....Daniel Fishor informs us that Mr. Pomeroy and others, who have some connection with the Oswego Iron Works, in Clackamas county, recently located a number of claims in the vicinity of Gold Hill, and proposes prospecting them at once for iron.

UTAH.

CONCENTRATES.—Salt Lake *Tribune*, Oct. 21. We learn that during the past season the old Telegraph company, at Bingham, has sent about 2,000 tons of concentrated ores to the smelters. This ore is concentrated by water, three tons in one, at a slight cost, and assays from 55 to 60 per cent lead and 15 to 25 ounces silver.

SMELTER.—The Park City smelter started up on Tuesday evening, and is now turning out bullion at a fair rate. The smelter is running ore from the Crescent company's mine, formerly known as the Pinyon-Climax-Rebellion. Forty-five tons per day of ore is about the quantity being reduced, the Crescent company will make things boom in Park City soon, as they have gone earnestly to work, and under the present management we may look for a big increase in the output of the property from what it is now doing.

ORE BODIES.—The mining districts of Lincoln & Bradshaw are coming to the front through late developments made there, and the finding of large ore bodies. These districts lie so far south that work can go on all winter, as snow does not fall deep enough in that locality to interfere with mining. These districts are a few miles southeast of Milford.

STONEMOUNTAIN.—Silver Reef *Miner*, Oct. 14: Ore shipments from the above property to their mill are being kept up regularly. This company has met with several drawbacks in the past 30 days, but are now coming down to business, with excellent and satisfactory results. Several bars of bullion have been shipped by Wells, Fargo & Co. during the month.

The Denver Exposition—No. 11.

[Editorial Correspondence.]

The San Juan region to, which somewhat full allusion was made last week, comprises the following counties: Hinsdale, San Juan, La Plata, Ouray, Dolores and Rio Grande. It was one of the mistakes of the management that these counties, so intimately connected geographically and geologically, were not also grouped together in their exhibits at the exhibition building. In our description we shall begin with

HINSDALE COUNTY.

Adjoining San Juan on the east is Hinsdale county, which bears the name of an honored Colorado pioneer. The county is of comparatively limited area, and exceedingly rugged and mountainous. The continentel divide or crest of the Rocky mountains forms a portion of its northwestern boundary. Uncompahgre, the third highest peak in Colorado, lifts its naked, vitreous head 14,235 ft. above the level of the sea. Yet, notwithstanding the roughness of the country, the people have spent sufficient money and time to secure good roads to all the principal points of the county. The first mines here, the Ute and the Ule, were located about 10 years ago, and work enough done to satisfy the owners of their value. But it was a year or two before it became safe for small parties to locate permanently in these mountains. The two mines mentioned, however, were developed and sold to their present owners, the Cooke Bros. & Co., in 1876, for $125,000. Other valuable mines were also located and more or less work done upon them.

The ores of this county are mainly argentiferous galena, containing a fair percentage of silver—which also occurs as native, ruby, wire and sulphide.

Free Gold Rock.

Free gold-bearing veins are occasionally met with, some of which pay largely, and several such mines have changed owners for large amounts. Arrangements have also just been made for working several placer mines.

Coal and Iron.

No coal has yet been found in this county, but there are 15 brick charcoal ovens, the products of which are used at the several smelting works. These ovens turn out about 1,600 bushels each week.

Furnaces.

There are four smelting plants in this county, only one of which, that of the Crookes at Lake city, is running. The ores from the Ute and the Ule mines, already noticed, are treated at this furnace. The iron used for fluxing by the Crokee Bros. is taken from a deposit of bog-iron ore belonging to the furnace company, covering an area of 20 acres, and of unknown depth. We are told that this ore assays on an average three ounces of gold to the ton, which of course goes with the bullion product of the furnaces. These works are carried on very systematically. About 40 tons of ore are treated daily. The zinc press is employed here for obtaining the silver—the lead which accompanies the concentrated silver is thrown off by cupellation—the pans used for that purpose are six feet in diameter. The gold goes with the silver into the bullion and the lead remaining after the silver and gold is removed is purified and sent to Chicago and New York, where it is manufactured into tinfoil by the Crooks' Bros., who have practically a monopoly of that manufacture in the United States. They are enabled to control it by the skill derived from nearly 30 years' experience in the business, and by virtue of several patents which they hold. A 1,300-pound nugget is shown from the Ute mine.

The Palmetto Co. and its Process.

This company owns the only stamp mill in the county and crushes its ores dry. Before crushing the ores are passed through a Bruckner revolving dryer, from which they go automatically to the stamps. From the stamps the pulverized material is taken by a conveyor to a Bruckner roasting furnace, where it is subjected to a chloridizing roast, by the addition of 10% of its weight of salt. Here the lead, which must not exceed 12% for this process, is vaporized, the iron oxidized, the gold released from its sulphur and iron, the silver chloridized, and the copper also converted into chloride, with the exception of a very small portion, which must necessarily become oxidized. The roasted product is next placed on a cooling floor, from which it goes to wooden leaching vats, where the mass is agitated and triturated in water. This process concluded, the pulp is allowed to settle, carrying with it all except the copper, which is held in the solution and drawn off with a syphon into precipitating vats, where it is collected by iron, old scrap iron being employed.

The pulp, which now contains the chloride of silver and the gold, is next placed in canvas bags, from which the remaining copper, saturated with water, is drained off. The pulp is then subjected to another leaching process, with hyposulphite of soda, by which the silver chloride is taken into solution, and afterward precipitated by sulphide of calcium, by which the silver is thrown down in the form of a sulphuret. The pulp is again drained in canvas bags to secure the last particle of silver. After that, and as a final process, the pulp, especially if it contains free gold in quantities sufficient to make it an object to save it, is placed in a common amalgamating pan, when it is amalgamated with quicksilver, which takes up the gold. The amalgam is then retorted, melted and run into gold bars.

Another Process.

The ore of the Dolly Varden mine is treated by a similar process to that employed at the Palmetto mine. This ore, however, contains no appreciable quantity of lead. The vein is a very narrow one, only four to nine inches thick, but its average assay is nearly 500 ounces in silver, in addition to a small quantity of gold and some copper. The ore is crushed by a rock breaker and rolls, and subjected to a chloridizing roast. The roasted product is then placed in tanks, where it is agitated in water, by which treatment the copper salts are taken into solution. This solution is then drawn off and the copper precipitated as at the Palmetto works. The pulp is now treated with a cold solution of hyposulphite of soda, which takes into solution the silver, which solution, in turn, is drawn off and the silver precipitated by (probably) sulphide of calcium as a silver sulphide. This sulphide is placed on sheets of iron, which are exposed over a slow fire, where the sulphide is thoroughly dried, assuming a granulated form, much like common blasting powder. In that condition it is placed in plumbago crucibles holding about two gallons each, in which, after being subjected to a furnace heat about six hours, in connection with proper fluxes, the silver is separated from the slag and poured off into molds. The pulp, after it has been leached of its copper and silver, still retains the gold, if any is present in the ore, which must be obtained by amalgamation in any ordinary amalgamator.

A New and Interesting Find

Was made in this county a short time since, which is as yet quite a puzzle to the miners and scientists hereabout. Mr. John S. Hough, after sinking a shaft 30 ft. deep through rock containing large amounts of white carbonate of iron, came suddenly upon a very peculiar mineral, which had much the appearance of volcanic slag—an idea that was strengthened from the fact that only half a mile distant was an immense deposit of black obsidian. Subsequent developements show that this mineral generally occurred in large nodules, imbedded in a hard form of carbonate of iron. At a further depth of 38 ft. the mineral gave out, and a smooth, level, contact floor of iron, (sesque-oxide) and lime occurred, much like the floor under the Leadville mines. Various assays of the minerals gave about 26% of copper and from 100 to 300 ozs. of silver to the ton. The discovery created quite an excitement, and a party of Leadville miners soon came over and offered $150,000 for the "find;" paid down $25,000, and expended several thousand more in drifting from 24 to 30 ft. in various directions, without finding any walls or change in the character of the deposit. In the meantime the Leadville party took up and bought most of the adjoining ground, and concluding from the evidence of their prospects, they had plenty of ground of their own, equally as good as the original discovery, declined to pay the balance of $125,000, forfeited the money paid and the ore on the dump. They are now at work opening up their own ground, while Mr. Hough, with $25,000 in his pocket, is shipping his big ore dump to the smelters at Lake City and Pueblo, and realizing nobody knows how much, but quite sufficient to make him feel happy with the entire transaction. The nature of the deposit as well as its character is still a matter of much interest to scientists and experts, and its further development will be closely watched. A large amount of the ore from this find occupies a conspicuous place in the Hinsdale exhibit.

Further Exhibits.

Fine native and effervescent alum, also sulphur and black manganese in great abundance, is found in this county and placed on exhibition. There are some free milling gold ores shown. Carbonate of lead is found to some considerable extent. Several fine specimens are on exhibition. The principal mine which carries this mineral is the Highland Chief—these sand carbonates—which is not yet developed to any considerable extent. From three furnace runs the following reports are given: Silver 8, 18 and 47 ozs. respectively, with from 40 to 60% of lead.

Among the exhibits we were shown a vial containing 16 ozs. of free scale gold, without any appearance of being water-worn. This gold was the result of four days' washing with a pan by two men, and forms another most

Valuable and Interesting Discovery.

At a point near Uncompahgre peak, within a few miles of the summit ridge of the Rockies, and at an elevation of over 13,000 ft., between two porphyry crags 50 ft. high, there is a depression about 30 ft. wide, on which occurs a mass of decomposed material, consisting of silica, feldspar, white carbonate of iron, iron pyrites and gold. The material is quite yielding, can be readily moved by a shovel with very little picking, like easily worked gravel. The gold in this mass is evidently in place, and could not have been disturbed, as, aside from its having no appearance of being water-worn, long strings of wire gold several inches in length are constantly being met with all through the mass, which never could have withstood any action of water other than percolation. The deposit is upon rising ground, so that two parallel tunnels have been run into it about 30 ft. long each and 20 ft. apart. In one of the tunnels a shaft has been sunk to the depth of 40 ft. Both tunnels and shaft continue all the way in the same material, and, so far as can be seen, of equal richness in gold. The 16 ozs. of gold shown were panned out of the dump heap from the tunnels and shaft. The result of the pan washing varied from 50 cents, the lowest, to $1.50 and more to the pan, mostly in small flakes. A rewashing of the tailings showed considerable fine flour gold. The amount of material already developed is immense, and at such a yield must represent quite a fortune. The deposit can be reached at a depth of about 1,000 ft. by a 600-ft. tunnel if it continues to such a depth. The find is certainly a most valuable as well as extensive one. Measures are being taken to properly work it. Of course extensions have been taken up. The discovery was made only a few weeks since.

A Most Creditable Evidence

Of the culture of this distant mountain locality, perched upon the very summit of the Rockies, is the fact that, although the county does not contain over 2,200 people all told, yet Lake City, its county seat, has already commenced a two story, $30,000 schoolhouse, the lower part of which is already finished and occupied, and well provided with all needed fixtures and educational facilities. It is built of brick, with cut stone trimmings.

If we are not mistaken, Mr. Wm. Penn Harbottle, the commissioner for this county, a gentleman of culture and refinement, is entitled to much credit in this important public improvement. That gentleman has certainly shown much zeal and energy in getting up the Hinsdale exhibit, which is ornamented with 160 stereoscopic views of the scenery, mines, etc., in the county, besides a large number of photographic, views of the more important localities, including one each of the schoolhouse and town.

W. B. EWER.

New Mining Region.

From the *Bedrock Democrat* (Baker City, Oregon), we take the following:

For some time past there has been quite an excitement in western Idaho over the discovery of rich ledges of gold and silver ores in Washington district, Washington county, Idaho, but it was not until last week that any definite information could be received in this section concerning it. It seems that these rich deposits of ores are traceable from Ruth district, in Idaho, to the mouth of Burnt river, in this county, about 55 miles southeast of this city. The deposits are to be found principally on Danite creek and the heads of Ness and Man's creeks. The ores consist of carbonate and chlorides, and consequently are smelting ores. There have been several men in the section from Leadville and various parts of Colorado, and the reports they received from ores sent back to those points have been very satisfactory, and men are flocking in from that section. The ore is different from any ever before found in this part of the country, but is very near like that of Leadville. It contains large quantities of silver and copper. Alex. Tartar, an old settler of this county, was in town last Saturday with some specimens of the ore, and seems highly elated over some ledges recently found by himself and partner, Mr. Hobbs. When he left there were over 135 ledges recorded in that district. From what we can glean from various sources, it seems that there is to be another Leadville in the new district.

"Crackle" Glass.

An ingenious process for producing glass with an iced or crackled surface, suitable for many decorative purposes, has been invented in France by Bay. The product appears in the form of sheets or panes, on one side of which is smooth and glossy like common window glass, while the other is rough and filled with innumerable crevices, giving it the frozen or crackled appearence so much admired for many decorative purposes. This peculiar crackled surface is obtained by covering the surface of the sheet on the table with a thick coating of some coarse-grained flux mixed to form a paste, or with a coating of some more easily fusible glass, and then subjecting it to the action of a strong fire, either open or in a muffle. As soon as the coating is fused, and the table is red hot, it is withdrawn and rapidly cooled. The superficial layer of flux separates itself in this operation from the underlying glass surface, and leaves behind the evidence of its attachment to the same in the form of numberless irregularities, scales, irregular crystal forms, etc., giving the glass surface the peculiar appearance to which the above name has been given. The rapid cooling of the glass may be facilitated with the aid of a stream of cold air, or by continuously projecting a fine spray of cold water upon it. By protecting certain portions of the glass surface from contact with the flux with the use of a template of any ornamental or other desired form these portions will retain their ordinary appearance, and will show the form of the design very strongly outlined beside the crackled surface. In this manner letters, arabesque and other patterns in white or colored glass can be produced with great ease and fine effect.

Zircon.

A Description of the Mineral.

Major W. F. Hillebrand and Whitman Cross, of the United States Geological Survey, communicates to the *American Journal of Science* some facts about the minerals of the Pike's Peak region, Colorado. They have the following to say about zircon:

G. A. Konig has described and analyzed zircon from two occurrences of the Pike's Peak district, in one case the mineral being associated with astrophyllite, and in the other with Amazon stone. In one of the instances we have to describe, the zircon is intergrown with large crystals of flesh-colored microline in one of the localities above mentioned, and is thus analogous to the latter occurrence noticed by Konig. There were many loose crystals in this cavity, but a few were found penetrating or imbedded in the microline. The crystals described by Konig showed both pyramid and prism, but the prism is entirely lacking on all of our specimens. Some crystals are more than an inch in diameter, and these large ones especially are often mere aggregates of numerous small pyramids grown together with a common crystallographic orientation. The lateral edges of such crystals are often continuous, but the terminations are made up of many small pyramids. Although the pyramid is the only prominent form, one can notice, on looking at the terminations in the right position, a minute reflecting surface on each perfect apex. A closer examination with the loupe shows it to correspond to the basis, but all observed surfaces are too small to admit of certain determination.

Near the Pike's Peak toll-road, about due west from Cheyenne mountain, a prospect tunnel, in following a vein-like mass of white quartz in granite, has disclosed a number of interesting minerals. The main body of the quartz is pure white in color and contains only traces of galena and chalcopyrite. Within this body, however, is a second smaller vein, coexisting likewise chiefly of white quartz, but carrying in it a number of other minerals, the most abundant of them being zircon. The boundary between the two masses of quartz is sharply drawn, but the development of the tunnel is not extensive enough to show clearly the relation of the two bodies.

Throughout the greater part of the vein the zircon is imbedded directly in the quartz, and is so abundant that a cubic inch of the latter mineral contains from 25 to 100 crystals and particles of zircon, varying in size one center meter downward. In parts of the vein, however, are small, irregular spaces filled with a soft, yellow foliate mineral in which are imbedded very perfect crystals of zircon. Fluorite and a white foliate mineral are sometimes associated with the others. The two foliate minerals are as yet undetermined.

This occurrence is worthy of special notice on account of the perfection of the crystals and their transparency. Some of the crystals lying in the quartz are perfectly developed, but usually their growth has been more or less hemmed by the quartz, and many are fissured. The crystals imbedded in the soft, yellow material, however, are often absolutely perfect in form, and beautifully clear. The ruling color is a deep reddish brown with variations toward pink or pale honey yellow. A few crystals are of a deep emerald green, and spots of the same were noticed in some of the pink crystals.

The chemical investigation of this zircon shows it to be exceedingly pure, and the specific gravity of the transparent crystals is 4 709 at 21° C. The perfection of the crystals, with their transparency and color, make this occurrence of zircon one of the most beautiful known.

In a paper, which we hope may appear in this journal within a short time, we shall describe several minerals of the cryolite group, which occur in connection with a quartz vein in the neighborhood of a zircon locality. Most of these fluorides are identical with those associated with cryolite in Greenland. The body of mineral found is of small extent, but yields a large number of species. There are also several species more or less associated with the zircon, in the study of which we are now engaged.

A MINER HURT.—Yesterday morning, between 1 and 2 o'clock, Patrick O'Connor, a repairmen working in the Utah mine, was pretty badly hurt. He was at work in the incline, a short distance above the 1750 level. He was about to ring the signal-bell, when the giraffe came down, and to avoid it he stepped back into the pump compartment. He stepped a little too far and was caught by a projection on the pump rod, while the rod was on the down stroke. He was caught just above the hips and crowded against a post, where there was a space of but about eight inches. The up stroke released him in a few seconds, and he was assisted out of his dangerous position, taken to the surface and to his home. No bones were broken, and if he has not suffered internal injury he will come out all right in a short time. He was getting along well last evening.—*Virginia Enterprise.*

THE shipments of bullion last week were probably the largest ever reached in the history of this camp. The shipm ts of bullion, not including matte and ore for reduction, aggregated the handsome sum of $102,100. A camp that can show this output will do to tie to.—*Butte Miner, Montana.*

The Engineer.

Railways in Brazil.

From the *Jornal do Commercio*, of Rio de Janairo, we learn some interesting details of railway progress in the Brazilian empire. In January last there were in operation 2,431 miles, and in course of construction about 2,000 miles of railway. These roads embrace some 20 or 30 short lines, and branches connecting the principal seaport cities with interior trading points. There are no great trunk lines, but some of the roads will be eventually extended into lines of great magnitude. About one-half of this railway mileage was built and is now owned by the government. Another portion was built by private companies, the government guaranteeing the interest on bonds, and the balance was built by local subventions from the provinces and towns through which the roads run. The government guarantees are nearly all at seven per cent. interest, and are placed in England.

The *Jornal do Commercio* states that some of these railways are paying their guaranteed interest, and that the government liability is being gradually reduced. This paper also asserts with a great deal of energy that "the government of Brazil has never abused the system of guarantees, but, with regard to them, we have observed an amount of prudence bordering on timidity." When the Brazilian Congress granted guarantees to the first railway companies, viz., those of Pernambuco, Bahia and San Paulo (1855-7), the general revenue of the empire was but a little more than $20,000,000. In 1880 this revenue amounted to $60,000,000.

The empire of Brazil covers nearly one-half of the southern hemisphere. It is quite as large as the United States and Territories, leaving out Alaska. Its eastern boundary is washed by the Atlantic from 4½° N. to 33° S. of the equator. Its western limits extend to the small, turbulent republic on the Pacific. It embraces about 3,200,000 square miles, nearly all lying between the Andes and the Atlantic. The future possibilities of the great empire of the wise and good Dom Pedro—the only ruler wearing a crown in the western hemisphere—cannot well be exaggerated.

Canal Between Lake Superior and Lake Winnipeg.—The canal connecting Lake Superior with the Red river, Lake Winnipeg, Assiniboine and Saskatchewan, is being projected. At a convention recently held at Duluth, "the zenith city of the unsalted seas," it was agreed that steps should be taken to have the canal constructed with the least possible delay, and to urge Congress to order surveys and vote a sum sufficient to complete the work. Engineers estimate the minimum cost of the proposed canal to be $4,000,000, while the highest calculation places it at $10,000,000, exclusive of preliminary surveys. By means of about 40 miles of canal, with suitable locks and dams, it appears to be practicable to utilize 340 miles of deep water lakes and rivers now navigable for steam vessels, lying between Lake Superior and the Red river, and so to make a useful waterway for craft propelled by steam from the great lakes to the vast system of water routes in the valleys of the Red river, the Assiniboine, the Saskatchewan and their tributaries, which reach so large a part of Minnesota, Dakota, Manitoba and the northwestern territory, and are the natural highways to the richest and most extensive body of contiguous agricultural lands on the American continent. The construction of the canal, it is claimed, will afford an outlet by a through water route to the Atlantic seaboard for a stretch of arable country equal in dimensions to the entire Eastern and Middle States of the Union.

A Third Tunnel Through the Alps.—The project for constructing a third railway tunnel beneath the Alps under Mont Blanc already meets with considerable opposition, particularly on scientific grounds. Herr Heim, a Swiss savant of the Polytechnicum of Zurich, contends that the piercing of Mont Blanc would be a work of immense difficulty. In one part the tunnel would have to be cut through a formation of anhydrone gypsum, which swells on exposure to the air, and is almost impossible to stay. Moreover, the temperature of the galleries, judging from the experience of the St. Gothard tunnel, would be from a minimum of 86° Fahr. to a maximum of 122°.

Paris as a Seaport.—There has been recently a revival of the project of making a seaport of Paris. It is said to be seriously entertained in French engineering circles. If accomplished, the channel from Havre to Poissy will be cut down to allow ocean steamers to go up to the latter point, which will deepen the harbor at Poisay, and there will be a series of locks that will convey the vessels to Paris. The plan is regarded as feasible, and it is estimated that the outlay would not exceed fifty millions of dollars.

The Suez Canal.—The Suez canal is one of the most valuable pieces of property in the world. The net profits last year were over $5,000,000. This was an increase of over 28% over the profits of the previous year. Each ship that passes through the canal pays a little over 20 cents a ton.

Useful Information.

Wood Finish.

Richness of effect may be gained in decorative woodwork by using woods of different tone, such as amaranth and amboyna, by inlaying and veneering. The Hungarian ash and French walnut afford excellent veneers, especially the burls of gnarls. A few useful notes on the subject are given by a recent American authority. In varnishing, the varnishes used can be toned down to match the wood, or be made to darken it, by the addition of coloring matters. The patented preparations known as "wood fillers" are prepared in different colors for the purpose of preparing the surface of wood previous to the varnishing. They fill up the pores of the wood, rendering the surface hard and smooth. For polishing mahogany, walnut, etc., the following is recommended: Dissolve beeswax by heat in spirits of turpentine until the mixture becomes viscid; then apply by a clean cloth, and rub thoroughly with a flannel or cloth. A common mode of polishing mahogany is by rubbing it first with linseed oil and then by a cloth dipped in very fine brickdust; a good gloss may also be produced by rubbing with linseed oil, and then holding trimmings or shavings of the same material against the work in the lathe. Glass paper, followed by rubbing, also gives a good luster.

There are various means of toning or darkening woods for decorative effect—logwood, lime, brown soft soap, dyed oil, sulphate of iron, nitrate of silver exposed to sun's rays, carbonate of soda, bichromate and permanganate of potash, and other alkaline preparations are used for darkening the wood; the last three are specially recommended. The solution is applied by dissolving one ounce of the alkali in two gills of boiling water, diluted to the required tone. The surface is saturated with a sponge or flannel, and immediately dried with soft rags. The carbonate is used for dark woods. Oil tinged with rose madder may be applied to hard woods like birch, and a red oil is prepared from soaked alkanet root in linseed oil. The grain of yellow pine can be brought out by two or three coats of japan much diluted with turpentine, and afterward oiled and rubbed. To give mahogany the appearance of age, lime water used before oiling is a good plan. In staining wood, the best and most transparent effect is obtained by repeated light coats of the same. For oak stain, a strong solution of oxalic acid is employed; for mahogany, dilute nitrous acid. A primary coat, or a coat of wood fillers is advantageous. For mahogany stains the following are given: Two ounces of dragon's blood dissolved in one quart of rectified spirits of wine, well shaken, or raw sienna in beer, with burnt sienna to give the required tone; for darker stains boil half a pound of madder and two ounces of logwood chips in one gallon of water and brush the decoction while hot over the wood. When dry, paint with a solution of two ounces of potash in one quart of water. A solution of permanganate of potash forms a rapid and excellent brown stain.—*Building News.*

The New German Magazine Gun.—This weapon, which is considered by the German government to have proved itself the most suitable military repeating rifle, is the invention of Messrs. Mauser, the originators of the present German regulation rifle. The magazine consists of a tube contained in the stock, and has a spiral spring which keeps the cartridges up to the breech action. When the bolt is withdrawn, a cartridge—which has been forced out of the magazine by the spiral spring—is raised up to the level of the cartridge chamber, into which it is driven by the bolt as it returns. The whole action of loading is comprised in the backward and forward motion of the bolt. In order to avoid waste of ammunition, a lever is attached to one side of the action, by which the magazine can be instantly closed, the gun being then loaded and fired as an ordinary breech-loader. The reloading of the magazine is stated only to occupy a few seconds. This system can be applied to the Mauser rifles of 1871 model, now in use, at very small cost. Two thousand of these weapons are in course of construction, and will be served out as quickly as possible to one of the grenadier regiments now quartered in Spandau.

The census of 1880 gives some interesting data relative to the number and size of farms in the leading agricultural States. Illinois is at the head of the list as to numbers, having 255,741 farms, Ohio comes next with 247,189; Missouri third with 215,575, and Indiana, Iowa, Kentucky, Michigan, Kansas and Wisconsin follow in the order named, the last having 134,332. Of farms containing more than 1,000 acres the greater number are in the Southern States and California. Kentucky has 1,112 such farms, while Illinois has but 649 and Ohio only 252.

Simple test of oil to discover traces of adulteration: Take an equal quantity of oil that you know to be pure and of the oil to be tested, and heat them to about 250° centigrade. The color will then decide the question of adulteration, as pure olive oil is of a light, delicate color and remains so, while adulterated oil grows dark rapidly. The pure olive oil also has a fresh odor, not unlike that of strawberries, when heated, while all other oils have a most disagreeable odor when heated.

Woolen Mill Machinery.—The statistician makes known on the authority of good judges that a woolen mill requires thorough renewal every double decade. There are altogether 9,000 sets of woolen machinery in the country. The number worn out and replaced every year is estimated at 450 sets. This includes 1,300 or more cards and spinning mules, with 10,000 to 15,000 looms. The price of mules varies from $750 to $900, according to the number of spindles. To replace the mules worn out every year the sum of nearly $1,250,000 is expended. The average durability of the machinery of a mill is about 20 years. The durability of different pieces of machinery varies. A set of cards used carefully may last half a century. The clothing on them may be renewed every five years. Looms are long lived. They may continue in use 50 years, but generally 20 years' service is about as much as they can render. The mules' average time of durability is 15 years. A set of cards comprises generally three to four separate carding machines. In manufacturing different styles of woolens there are 35 or 40 different processes, and nearly every process calls into use a different kind of machine.—*Providence Journal.*

To Prevent Silverware from Tarnishing.—Solid silverware, as well as plated goods, grow dark and tarnished in a very short time when exposed to the air, and even when put away in a dark place. This is especially the case where hard coal is used in the house or neighborhood, as the sulphur in the coal, liberated by heat, is sure to stain all the silverware within reach. This annoying tarnishing can be entirely prevented by painting the silverware with a soft brush dipped in alcohol in which some collodium has been dissolved. The liquid dries immediately and forms a thin, transparent and absolutely invisible coating upon the silver, which completely protects it from all effects of the atmosphere, etc. It can be removed at any time by dipping the article in hot water. This recipe has been in use for some time in the large establishments at London, where most of the goods in the show-cases are protected in this manner.

Cherry Wood.—A large portion of the wood manufactured and forwarded under the name of cherry proves to be principally sweet gum. For many purposes it is really superior to cherry, but when the difference in market value is taken into consideration the transaction is questionable.

Good Health.

How We Digest.

To make the process of digestion simple, let me say that it begins in the mouth and ends in the lungs. A man swallows a mouthful of bread. We follow it from his mouth down through the œsophagus to his stomach. It now, by a peculiar motion of the stomach, is moved about in the stomach, and as it touches here and there, gastric juice starts out, like sweat upon the forehead, and wets the bread.

After a couple of hours of revolving about within the stomach, the bread is changed into something that looks like buttermilk. This is chyme. Now the gate at the right end of the stomach opens and lets this chyme pass through the first parts of the intestine. These two liquids are poured in, one from the liver—the bile—the other from the pancreas—the pancreatic juice. These induce certain changes in the liquid bread which makes it resemble milk. Now it is known as chyle. Innumerable little mouths which open within the intestine suck up the milk or chyle, carrying it to a small canal—the thoracic duct, which lies upon the back bone—and through this it runs up to the upper part of the chest and is poured into a large vein just under the left collar-bone. Through this vein it reaches the right side of the heart, and is then forced into the lungs, when it comes in contact with the air. Now a wonderful change comes over it. This is produced by the addition of oxygen to the milk-like fluid. For a given quantity of this chyle a still larger quantity of oxygen is added, and the compound which comes of this union between the bread and the oxygen is the nutriment which supplies the wants of the system. What takes place in the lungs is more important than anything that precedes it in the process of digestion.

For example, a man may live on fried salt pork, hot salaratus biscuit, and strong green tea (I don't know a worse dose); if he lives on the western plains and breathes pure air, he will have a purer blood, healthier skin, and will be freer from humors, than another man who lives upon the choicest grains and fruits, but who constantly breathes the air of a close, furnace-heated house. In other words, we may truly say that, in considering the great function of digestion, the lungs really play a more important part than the stomach itself.

It is really vital that the first and last step in digestion should be well done. First, chew well, and last, breathe well. If those two duties are well performed, a substantial contribution will be made to our welfare."—*Dr. Dio Lewis.*

Poisoned by Lima Bean Roots.—The family of F. L. Kellogg, at Goleta, Santa Clara county, were dangerously poisoned a short time since by eating the roots of Lima beans, which they happened to discover were very palatable,

Effects of Too Much Brain Work for Children.

On April 28th, Dr. Richardson, F. R. S., delivering a lecture on "National Necessities as the Bases of Natural Education," before the Society of Arts, brought forward, writes F. C. S., the following extract, which happened to be a report of the chairman of the evening, Mr. Edwin Chadwick, C. B., to the British Association in 1860, to show what an evil effect too much brain work, without a proportional amount of industrial occupation to support it, has upon young children:

"In one large establishment, containing about 600 children, half girls and half boys, the means of industrial occupation were gained for the girls before any were obtained for the boys. The girls were, therefore, put upon half time tuitions; that is to say, their time of book instruction was reduced from 36 hours to 18 per week, given on the three alternate days of their industrial occupation, the boys remaining at full school time of 36 hours per week, the teaching being the same, on the same system, and by the same teachers, the same school attendance in weeks and years in both cases. On the periodical examination of the school, surprise was expressed by the inspectors at finding how much more alert, mentally, the girls were than the boys, and in advance in book attainments. Subsequently industrial occupation was found for the boys, when their time of book instruction was reduced from 36 hours a week to 18; and after a while, the boys were proved, upon examination, to have obtained their previous relative position, which was in advance of the girls."

Shutting up Children.—The London *Lancet* relates a distressing case of suicide of a boy 10 years old, who had been shut up in his bedroom as a punishment. The editor comments adversely on leaving children or young persons and the weakly or troubled in mind alone: "The solitary state is abhorrent to the nature and mind of man. Whether the brain be immature in its development or morbid in its state, it is wrong in a scientific sense—that is, opposed to the laws and teachings of physiological science—to leave it alone. The possibility—we will even concede the probability—of a subsidence of excitement is not a sufficient set-off against the dangers of a self-destructive intellectual activity. The mind always works to its own injury when it works alone. Reflection, introspection and self-examination are essentially abnormal processes. The proper action of mind is on the outer world, or on such conceptions of fact and object as may be readily corrected by present observation or experience. Abstract processes of thought are never safe for the young or the weakly and troubled in mind. Healthy activity, so far as these two conditions of mind are concerned, is directly relative. It is not good for man to be alone in any sense. We would therefore again protest against the recourse to solitary confinement as a punishment for children, and against 'seclusion' in any form for the unsound of mind. The two methods of treatment stand on the same footing, and they are both equally bad."

American Public Health Association.—We have just received a circular announcing the fact that the American Public Health Association will hold its tenth annual session at Indianapolis, Ind., commencing Tuesday, Oct. 17, 1882, and ending Friday, October 20, 1882. A number of interesting papers on sanitary subjects have been announced, and as more time will be devoted to discussion on this occasion than has been allotted at former meetings, we venture to say that considerable matter of unusual interest and importance will receive attention. The plan adopted of favoring and promoting discussions on the various subjects considered is worthy of favorable comment, and it is to be hoped that the members will take advantage of the opportunity thus offered for directing special attention to points of more than ordinary interest. The Secretary of the association announces that information in regard to transportation will be furnished by the Indianapolis local committee at an early date, and by a later bulletin from the Secretary, if required.

A New Method of Bleaching.—Messrs. Dobbie & Hutcheson have investigated the various methods of liberating chlorine and decomposing hydrochloric acid and chlorides with a weak electric current. They obtained the best results by moistening the goods with sea water and passing them between two slowly revolving carbon rollers, which were connected with opposite poles of a battery. Sodium hypochlorite was formed in the fabric, and on immersion in acid the bleaching was effected. Results were also obtained with dilute hydrochloric acid. Pure hydrofluoric acid also bleaches when thus decomposed.

The Sun Spots.—Herr S. Wolff has lately advanced, in the French journal *Kosmos*, the theory that the sun spots, instead of being cooler than the adjacent parts of the solar surface, as is generally believed by astronomers, represent parts of the sun that are vastly hotter than the bright portions of the solar surface. They are, according to Herr Wolff, regions so intensely hot that all the heat movements emanating therefrom have reached the intensity of the ultra violet, and these being invisible, the spots consequently appear dark,

Passing Events.

The miners in many parts of this State and Oregon are all ready for the season and are now anxiously waiting for good steady rains to set in to begin their work. So far very little rain has fallen, but at the time of writing there is every prospect of a good supply of water which will be enough to last some little time. Quartz miners as a general thing do not care very much for the rains, as in many cases it gives them more trouble in pumping than in drier weather. It is worthy of note to call attention in this place to a statement of a Nevada paper to the effect that the districts down in Southwestern Nevada are better prospected in the winter months than in the summer, because the snow furnishes water. This is a hint that prospectors can take at this time, when they are looking about for a place to put in their time for the winter.

Utah seems to be doing as much just now at bullion producing as any other region. Her mines are doing very well indeed, and the best proof of this is the fact that shipments of bullion are regular and frequent. New Mexico is perhaps attracting more attention than any other of the Territories. There seems to be a good deal of Eastern capital going into the different mining districts, and the territorial papers are jubilant over the fact that capital is coming in at last. There is, however, some complaint of the working of the mining law in that territory. People hold on to too much land. This is a complaint that comes from other places, too.

What Are Minerals?

An Enumeration of What the Mining Laws Recognize.

The term mineral, in its most comprehensive sense, includes all inorganic substances having a definite chemical composition, and so applied in the construction of Sec. 2318 of the Revised Statutes of the United States would subject all of the public domain to fall under the Mining Act. This section, 2318, is the one declaring mineral lands reserved, and is as follows: "In all cases lands valuable for minerals shall be reserved from sale, except as otherwise expressly directed by law." All mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are declared free and open to exploration and purchase.

A reasonable construction of this section of the United States mining laws will hold it to embrace only such lands as contain valuable deposits of metals and other substances which give the same a special value greater than that of land containing limestone deposits in any of its forms. In the sense in which the term mineral was used by Congress it seems difficult to find a definition that will embrace what mineralogists agree should be included. The several authorities consulted in this connection seem to find it an easier task to determine what is, than what is not mineral. After a careful examination of this matter the Government authorities have reached the following conclusion as to what constitutes a "valuable deposit:"

"That whatever is recognized as a mineral by the standard authorities on the subject, where the same is found in quality and quantity to render the land sought to be patented to be more valuable on this account than for purposes of agriculture, should be treated as coming within the purview of the Mining Act of May 10, 1872."

The language of the statute is so comprehensive and capable of such liberal construction that the conclusion can hardly be avoided that Congress intended it as a general mining law, "to promote the development of the mining resources of the United States," and to afford a method whereby parties holding possessory rights under local laws and regulations could secure title to tracts containing valuable accretions of mineral substances, except where a special law might intervene, reserving from sale, or regulating the disposal of particularly specified mineral-bearing lands. The word "deposit" has always been construed by the Land Office to be a general term, embracing veins, lodes, ledges, placers, and all other forms in which valuable metals have been discovered.

In framing the statute, comprehensive words were used no doubt to include as well what might afterwards be discovered as what might be overlooked in an enumeration of minerals.

Public lands for the purpose of sale are divided into agricultural and mineral lands. The minimum price of the former is $1.25 and the latter $5.00 per acre; mineral lands exclusive of their valuable deposits are generally worth little or nothing. Prior to the act of July 26, 1866, it was customary for persons to take those deposits without respect to the rights of the United States. Congress then provided a way in which persons locating lands for mining purposes might acquire title, and other acts have since been passed promotive of the same end. These acts are liberally construed by the Government authorities so as to facilitate the sale of such lands; for in that way and not otherwise can they be made to contribute something to the revenues of the government, and controversy and litigation in mining localities, to a great extent be prevented.

It is taken for granted that miners understand that the ordinary substances, as gold, silver, copper, lead, etc. are of course locatable; and in this instance we intend only to point out what the law is in respect to such substances as might be considered doubtful; and if what we write here is clipped out and saved for reference by prospectors, it may save them some trouble in hunting up the questions involved at some future time.

Diamond-producing land for instance may be patented under the mining laws. In Brazil they are washed out of an agglomerate, composed of rounded white quartz pebbles and a light colored sand. Diamonds then are clearly "valuable mineral deposits," and the provision of the U. S. mining laws are as applicable to lands containing them as to lands containing gold and silver or other precious metals.

In a decision given as far back as 1873 the commissioner of the General Land Office recognized as minerals, borax, nitrate of soda, carbonate of soda, sulphur, alum and asphalt. In another instance it has been decided that borax cannot be entered under the agricultural laws of congress. The proceedings required are the same as called for in the case of patenting placer claims. As cinnabar and copper are found in "rock in place" rather than in the form of placers, parties desirous of obtaining patents for lands, valuable on account of the deposits of cinnebar or copper, must enter the same as lode claims when applying for patent.

As we stated in an article in last week's PRESS, gypsum is not a mineral within the meaning of the mining act. This is of similar formation to limestone, which underlies a great portion of the territory west of the Missouri river, and to reserve such land from sale as mineral would entirely prevent its development for agricultural purposes. Iron lands may be patented under the laws. Where the iron is found in lodes or veins, or in "rock in place," the proceedings to obtain patent are the same as in the case of vein or lode claims. Where the iron is not found in "rock in place," the proceedings to obtain Government title are the same as those prescribed by the act of Congress in the case of placer claims.

Kaolin (or porcelain clay) may be patented as mineral. It has been ruled also that lands which are more valuable on account of deposits of limestone or marble than they are for purposes of agriculture may be patented under the mining acts. This ruling was made in 1875, and there are some exceptions to it. It may be remembered by some of our readers that there was a contest in this State between the Southern Pacific railroad and the Kaweah limestone ledge mine. In the decision in this case, which was rendered in August, 1880, it was ruled that limestone deposits do not, as minerals, except land from railroad grants in terms similar to the one of the Southern Pacific railroad prior to 1872. Lands in California containing limestone, and useless for agriculture, can be purchased only under the timber and stone Act of June 3, 1878. In this case the claim was regularly located, recorded, work done on it, kilns erected, and application for patent made, all in due form. The land was, however, not treated as mineral, and was awarded to the railroad company.

Lands containing deposits of mica may be taken up in the usual way that any other mineral deposits are taken. It may be well to mention here that from the operation of the grants of the different railroad companies are excepted all the mineral lands, except those containing coal and iron, and mineral lands can only be acquired under mining acts.

Petroleum claims are located under the mining laws. Lands containing deposits of umber may be taken up under mining laws. The price per acre depends upon the character and formation of the deposit. If it is found in veins or in "rock in place," the same rates per acre must be paid as in the case of lode claims. If the umber is not found in veins or "rock in place," it is taken up as a placer claim, and $250 per acre paid for it.

Deposits of slate are taken up under the mining laws. Deposits of sulphur are also locatable.

Coal is taken up under a special law, to which it is not necessary at this time to allude at length. Paint stone is locatable under the mining laws. Oil comes under the same head as petroleum, and is a mineral within the meaning of the statutes. China clay and fire clay are also.

Saline lands are sold by the government under a special act of Congress, dated January 12, 1877. The provisions of this act, however, do not apply to any lands within the Territories, nor to any within the States of Mississippi, Louisiana, Florida, California and Nevada, none of which have had a grant of salines by an act of Congress.

In a decision given in 1877, the commissioner of the General Land Office recognized salt as a mineral and stated that lands containing valuable deposits of salt are excepted from the grant to the Central Pacific railroad. This decision was given on a test case in the State of Nevada.

Ashestos, plumbago, antimony, bismuth, cobalt, manganese, platinum, zinc, tin, nickel, cinnabar, and a host of others we might mention are minerals within the meaning of the United States mining laws.

A TERRIBLE TRIP.—The Bodie *Free Press* says: J. H. Sperling, assayer for the Great Sierra Mining Co., at Tiogo, came near losing his life a few days ago in a snow storm. The latter part of last week he left Bennettville to inspect some mines on Mount Gibbs, at the head of Bloody Canyon. A snow storm coming on he lost his way, and for three days and two nights he was without food or shelter, having neither blankets nor provisions. The only thing he had in the shape of food was a piece of tallow that he took with him to dope his snowshoes. Mr. Sperling's feet are badly frozen, and it is feared he may lose one of them. He will be taken to Lundy in a few days, and every care taken of him by the company.

THE closing quotations of copper, according to James Lewis & Son's Liverpool copper report, are as follows: Chili bars, £71 10s. to £72 for good ordinary brands. Ore, 14s. 3d., and regulus, 14s. 6d. per unit. The total visible supply of copper is 47,754 tons fine, against 51,430 tons on October 1, 1881, and 62,666 tons on October 1, 1880. So far this year Swansea has exported 46,870 tons of copper. Prices are well maintained just now at Swansea and Liverpool.

A Word to Subscribers.

Prompt renewal of subscriptions is the strongest support that newspaper publishers feel. It is, so to speak, "the most sustaining part" of a newspaper diet. We have much to be pleased at in connection with our large list of subscribers, yet there are some whom we trust can favor us more promptly in forwarding the renewal of their subscriptions, and we feel the necessity of soliciting all who like our paper, and are pleased to support us in our efforts to produce a worthy and progressive journal, to do the best possible in forwarding their subscriptions promptly and aid us in securing new ones.

The Great Copper Belt.

"The Mines of Lower California, Mexico."

Copper is found a few miles north of San Diego, in veins from 2½ to 3½ ft. wide, and within five miles of the Pacific. The ore runs from 5 to 15% copper, probably an average of 8%. Whether it would pay to mine and ship this ore, or mine, reduce and concentrate at the mine is yet to be proved; 12 miles south of the Mexican boundary line, 30 miles from San Diego, are found the first real paying copper mines, 3½ to 5 ft. in width and carrying ore with 15 to 20% in copper. This ore has been mined and hauled to San Diego and shipped to San Francisco, where from $50 to $60 per ton was paid for it. But for some unknown reason work was discontinued. Five miles from the coast and 100 miles south of San Diego, *via* the wagon road, a belt of copper is formed, carrying from 15 to 20% in copper, $3 to $6 in gold and $5 to $8 in silver per ton. This ore shipped to San Francisco commanded $60 per ton.

Foliated talc is found in these mines, samples of which have been shipped to Philadelphia, New York and Europe, for which $280 per ton was offered, provided 75 tons per month could be relied on by each of five different paper mills. It is used in the manufacture of wall papers, card-board and printing paper. In some of the mines there is from 15 to 20% of talc. Eastern and European paper manufacturers are now experimenting with it. Heretofore all, or nearly all, in use, has been imported from Japan.

But the "Great Copper Belt" of Baja California does not begin until you get about 175 to 200 miles southeast of San Diego. Between that point and Cape St. Lucas, there are said to be at least 100,000 copper mines, 10,000 of which from the very surface are good, being from 3½ to 8 ft. wide and giving from 25 to 75% in copper, $8 to $25 in gold and $10 to $55 in silver per ton. One mine, which has the greatest depth, say 300 ft., has averaged to pay $236 per ton from the surface. These veins are situated from the waters edge of the Pacific back for 20 miles and even further. It was formerly thought that the best mines were situated in the rolling, small mountains 15 to 20 miles back from the ocean, but late investigations go to show that some of the richest ore and best veins are within three to eight miles of good landing and shipping places on the coast. Nearly all of those veins carry their own flux in the ores.

The geological formation of the country is granite and gneiss. Belts of limestone, slate, schist and porphyry extend the whole length of the copper belt, running parallel with the coast. Dykes of horn blend are found between the belts of granite and slate and slate and schist. The ores vary, being carbonates of copper in one section, oxides in another. In others the ore is sulphurets of iron and chalco-pyrites, carrying in a few cases galena from silver and native gold, and in others showing native copper in large quantities.

The ore can all be worked in water jacket smelters, some of it can be crushed and concentrated, and the concentrations shipped. A custom water jacket furnace put up in San Diego or at San Quentin bay, 275 miles below, would have all the ore they could work. If such were built at either place a large number of the mines would be worked at once on a small scale, and the ore shipped to either point by the large number of coasting vessels now in the seal and abalone trade. As it is, only a very few of the veins are now located.

The "Base Line" R. R. from San Diego to Calabasas, in Arizona, via the Real del Castillo, Santa Catalina, mouth of the Colorado river. Altar, in Sonora, passes very near to this copper belt for 100 miles along its surveyed line. The branch from Real del Castillo to Ensenada, will probably be changed to leave the main line at Santa Catalina, and run from there to San Quentin bay, a better harbor, and directly through the heart of the copper belt. It is now said that work on this road will be commenced in November.

A few years since 60 tons of this copper ore was shipped to one of the Eastern copper works, and the proprietor of the works says that he made a grade of copper from it superior to that ever made from any other ore. He has spent $2,000 trying to trace the shipment back so as to know which mine produced the ore. This copper belt, 28 miles by 800, is undoubtedly the richest and most extensive in the world, and within a very short time must have great influence upon the price of copper. Iron, coal, salt, sulphur, plumbago, talc, alum, manganese, marble, gypsum and many other minerals are found along, in and on either side of this great belt of copper—all within easy reach of the sea; good landings and shipping points are found every 10 to 20 miles. Gold and silver are found in very rich mines in smaller hills by themselves, often coming into each other. The Marquey, Mescal, or paper plant (century plant or thousand aloe) is also found in great abundance. Thousands of tons of it can be had for rope, twine, paper and pulp.

THE agent for the PRESS, who recently visited Penryn, Dutch Flat, Reno and some intermediate points early in October, has since been too ill to report for our columns. Mr. Woodmansee continues the work for us in Nevada.

Mounting Engine Lathe Carriages.

[Written for the MINING AND SCIENTIFIC PRESS, by J. RICHARDS.]

Among many peculiarities of machine tool practice in this country the most marked is that of the method of mounting the carriages of engine lathes on what are known as V ways. Some tool makers do not employ such ways, notably among them Messrs. William Sellers & Co., of Philadelphia, yet the practice is uniform in New England, and in all cases where lathes are copied from the type known as the New England one. This matter is one of some importance in lathe construction, and is, moreover, one involving many things too intricate for popular understanding, and its discussion here must cover considerable space if all the various conditions are to be noticed. As just remarked, the V ways are a feature of American practice. Lathes are not made in this manner in other countries, and the circumstances which have led to its adoption are to be found, as I believe, in causes other than the mechanical operation of lathes. The writer was once a firm believer in this method of mounting carriages, and contended for its superiority over other methods, but found in the end that he had, in common with most persons who had not made a study of the matter, made the mistake of seeing and trying but one side of the question. In Sweden in 1876 a wager was made with the engineer of the State railway at Gothenburg that the carriages on his Whitworth lathes were not firm and could be shaken. To my astonishment they could not, and what was more, the carriages on the 18 in. and 24 in. lathes could be moved along easily by simply pushing them with one hand.

It was at the same time noticed the carriages of all but the largest lathes were moved by a crank and a pinion gearing directly into a rack. This circumstance led to a careful examination of the matter, extending over several years, during which time English, German, French, Swiss, Belgian and other lathes were examined. The conclusions reached are as follows:

Among the various kinds of tool slides, or, as we might say, the sliding joints in machine tools, none are made in this manner, with a single exception, that of the carriages of planing machines; but as these are held down by gravity alone, the analogy is not complete.

All other slides about lathes are made with positive gibs, and fitted to move positively throughout their stroke or range. The reasons for adopting and following this method of making lathe frames came, no doubt, from early practice in New England, when the frames were made of wood and the ways were strips of iron chipped and filed, or hand planed and screwed down on top of the wooden frames with carpenters' screws.

There was of course no means of gibbing down a carriage in such a case, besides the narrow bearing soon wore away in places, and the only means of securing guidance of a carriage was to hang upon it a weight to keep it down so long as the strains did not exceed the weight. This method answered very well so long as the method of turning iron consisted in the use of a fine feed, sharp pointed tools, files and emery sticks, with a minimum to cut off. It has, in fact, lasted to the present time in some of the New England shops, where lathes are now made with weights to hold the carriages on and in some cases with springs to perform the same office.

Another reason for the V ways is the economical or commercial one of cheapness. To those not familiar with tool making, it seems more expensive to make a lathe with V ways, but anyone who has kept cost accounts of such work knows better. I incline to the opinion that the expense of planing up two lathe frames, one with V ways and the other for a gibbed carriage is, as two to one in favor of the former. In the first case the lathe heads and carriage are mounted on the V ways, and these alone require exact dimensions, or rather position, because if there is no flat surface on top there is no exact dimension except the "pitch" between the ways. This can be secured from the cross-feed-screw of a planing machine and the bevil by "shape tools," so that as when the V ways are planed all the rest is merely truing up or smoothing.

For a gibbed carriage a lathe frame must be planed to exact dimensions "all over," especially when the edges of the frame are left square, as now seems to be the coming method. There is no smoothing up without exact dimensions; all must be done to gauges, and true, if the carriages are to have a positive and free movement; the greatest difference, however, comes when the frames and carriages are to be fitted up. With a frame having V ways there is but little fitting to be done.

The carriages slide on the ways whether they fit or not, or if fitted the surface of contact is so small the expense is but little in comparison.

The bottom of the frame ledges are planed it is true, and some kinds of gibs are applied, but not fitted to bear, which would be useless, because the narrow ways soon bear down where most used, and gibs do no good.

The use of springs is a sufficient proof of this, or if a better one is wanted, a stiff pry bar, under a carriage will show the result of such mounting.

So long as the strains are not enough to lift the carriage it moves steadily enough, but in boring, and for the methods of turning on the Pacific coast these "weight" and "spring" keepers do not answer. It is sometimes argued, and with reason, too, that by clamping the sliding head of a lathe on V ways the lathe frame is firmly bound together at that point. This is, no doubt, a matter of some importance, if lathe frames are made with two rails or an open box connected by cross-girts, but not otherwise.

This method of making frames may, like the V ways, I think, be traced back to the wooden frames made 40 or more years ago in New England. For a long time after iron framing for machines came into use in this country they were made more or less in imitation of the carpenters' work that preceded them. Straight lines, right angles, beads, panels, mouldings, etc., in imitation of joiner and cabinet work, could be seen throughout. In the case of many machines, and mainly from the examples of Messrs. William Sellers & Co., and Messrs. Bement & Son, of Philadelphia, hollow box frames came into use for most machine tools, but not for lathes. These continued to be made, as before remarked, in very close imitation of the old wooden ones, with two side rails and cross-girts at intervals. This is perhaps the weakest section that could be adopted for a lathe frame, and is particularly unsuited for resisting torsional strains, to which lathe frames are especially subjected.

If frames are made in this way there is no disputing the importance of "tying" them together by a sliding head or any other means available. One objection to V ways is the force required to move a carriage on them. It is common to disguise this matter by gearing the hand motion, so the carriages move very slowly, in some cases not more than two inches for each revolution of the crank; but this again causes inconvenience in cutting screws, for example, when the carriage is to be run back by hand. On a lathe properly arranged there is seldom any use for a "backing belt," so a quick hand movement is a very important matter.

From some experiments recently tried between what are called Putman lathes and those made by the San Francisco Tool Co., the former being mounted on V ways in one case, and on broad, rectangular guides in the other; it was found the force required to move them was more than two to one in favor of the gibbed carriage, although it was much the heavier of the two. A fact of some significance in this matter is that the best makers of lathes have in some cases adopted carriage ways with beveled sides but flat on top, so the weight is taken upon this flat surface and at right angles to the strain. This requires better fitting, the carriages move easier, the amount of wear is reduced, and gibs can be employed with effect for sometime before the carriages wear down. It is a common remark, and a fact, too, that "the wider the flat part the better"; from which a fair inference is that the beveled part had better be omitted altogether, and substituted by a square bearing at the edge of the frame. I think a fair conclusion in the whole matter to be that in view of the method of making lathes now coming into use, the carriage should have its principal bearing on top—a wide, flat surface that can be kept dry without danger of abrasion or wear.

2.—There should be gib pieces the whole length of the carriages, both against the edges of the frame and at the bottom, and the carriage should be scraped on so as to move smoothly and positively from end to end, like the tool box of a planing machine, or any other case where tools are traversed.

3.—That the flanges of the frames instead of being beveled, as is the English custom, should be left square to avoid the friction that is always present in angular joints and when the stress falls on inclined surfaces.

As before remarked, the expense of fitting lathes in this manner is something more, depending, of course, to a considerable extent upon how true the planing is done; but the result in working and in durability amply compensates for the added cost. It may add something to the force of these conclusions to explain they are not inferences, nor based upon a few experiments, or a narrow experience. I have taken a number of these V frame lathes to England, in one case three of different sizes, and from different makers, to be operated with, and in comparison with English lathes, and know "whereof I speak."

Our American machine tools for planing, drilling, milling and so on are well designed in most cases, are superior in efficiency to corresponding types in other countries. This is especially true of planing machines; there has been added to these many points of improvement that have not found their way to Europe, or at least are not commonly known there, but the same remarks will by no means apply to our engine lathe.

The V ways: Spindle bearings of brass or other soft metal; the lead screws placed at the back instead of at the front; carriages held down by springs or weights; the complication and inaccessibility of the apron gearing; want of power in the spindle gearing are all features that must be abandoned before American tool makers can compete successfully in what may be called the neutral markets of the world.

In connection with these remarks it will be fair to say that all lathes made in this country are not constructed as indicated above. At Philadelphia lathes are now made with hardened spindles and bearings, and the stronger

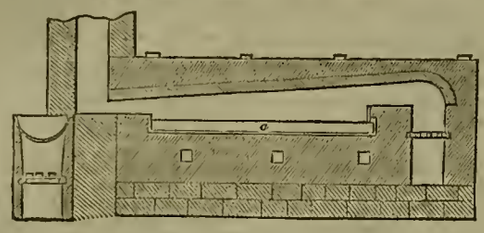

FIG. 1.—SECTIONAL ELEVATION OF LEAD SOFTENING FURNACE.

class of lathes, those for turning car axles, for example, are not made with V-ways.

The screws are in many cases placed at the front, or what is better, within the frames, yet the general practice of the country taken as a whole, is at this time of the New England type.

The efficiency of lathes can be best determined by the cost of doing good work on them, both heavy and light, and some valuable suggestions would come from facts respecting performance if it could be fairly ascertained. In England the peculiar system of "piece work" done there leads to very exact information respecting the cost of turning, there being "constants," so to speak, for turned surfaces of various kinds, from which estimates are made up. This, perhaps, more than any other cause, would lead to a modification of lathe designs.

The Grant Smelter at Denver.

During our recent visit at Denver we took occasion to visit the new and extensive smelting works then and still in progress of construction near that city, under the direction of Messrs. Grant, Eddy & James. This company

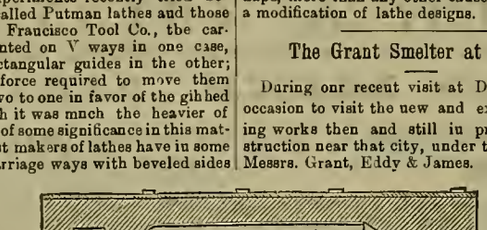

FIG. 2.—PLAN OF BED OF LEAD SOFTENING FURNACE.

has, for some time, been running a large plant of smelting works at Leadville, which was recently destroyed by fire, and this company is rebuilding, as above, near Denver city. They have already several furnaces in blast, and have on hand 48,000 tons of ore, a portion of which is at their old Leadville works, but will be transferred to the new plant. Besides this large amount they have in transit and under contract to be delivered before January 1, 1883, at their works in Denver, 30,000 tons additional. Their supply is principally from Summit, Park and Gunnilon counties, and from New Mexico, Utah, Wyoming and Montana Territories. Since the destruction of their works at Leadville they have been able to treat only about sixty tons of ore per day, but are now enabled to treat three hundred tons per day—of which 240 tons are treated at Denver. During the past three months this firm have purchased and shipped $1,245,000 worth of ore. They have also reduced $343,000 worth of ore to bullion. Their works at Denver are perfectly arranged and are certainly fire-proof. They employ 150 men at Denver and a like number at Leadville in their smelting works.

These works are already constructed on a very large scale, and so arranged that additions can be added to any desired extent. The casting for the water jacket furnaces, and all the iron work for the extensive buildings connected with their works were made by the Colorado Iron Works, which large establishment is located in the immediate vicinity of these smelting works.

It is said that over 50 mines are now being successfully worked within a radius of two miles from Tombstone, Arizona.

Softening of Lead by Oxidation.

The method of softening lead by atmospheric oxidation or calcination is conducted in Europe in a reverberatory furnace, with a low arch or crown, and fitted with a shallow cast-iron bottom, as indicated in the engravings, or other bottom, formed so as to be impervious to the percolation of molten lead. The charge of from 6 to 10 tons of lead is either melted in an adjoining pot before its introduction into the softening furnace proper, or the pigs of lead may be at once inserted upon the hearth of the furnace and there melted, upon which the temperature is raised above the melting point of lead, and thereby the more oxidizable metals, as antimony, arsenic, copper, tin, etc., along with some lead, are oxidized, and collect as a kind of dross or slag upon the surface of the metal, when the temperature is lowered and the dross is raked or skimmed off. The heat is now again increased with the production of a further proportion of dross, when the temperature is lowered as before for its removal, by skimming, and these operations of oxidation and of skimming off the dross are repeated until specimens of the metal taken out for trial exhibit the required degree of softness and malleability, the surface of the metal in the furnace also generally indicating this condition by presenting a blue iridescent color and crystalline texture instead of being rapidly covered with a dull bluish-white incrustation of oxide of antimony, as presented by the hard metal.

The duration of the softening process depends upon the purity or relative hardness of the original lead. Thus, while from 18 to 24 hours will suffice to soften some varieties, others and more impure specimens, such as those produced from the smelting of lead slags in the slag hearth of Derbyshire, or the hard lead produced from Spanish ores, requires considerably longer time to soften, the period in such cases extending to some 14 days' of constant attention.

At Freiberg, in Saxony, the softening is effected in a reverberatory furnace, to the hearth of which a blast of air is supplied by a pair of twyers, for the oxidation of the impurities.

The *slag* or *dross* removed from the surface of the metal during the softening process differs much in physical qualities, but often presents a dull brownish color, is hard and heavy, consisting, as previously indicated, largely of the oxides of antimony, copper, tin, lead, etc., and if treated along with carbonaceous matters in a blast or reverberatory furnace, it yields a *hard* lead, from which, however, a proportion of soft lead may be obtained by subjecting it to a repetition of the above softening process, or such hard metal may be at once employed as an inferior metal for the manufacture of bullets, inferior type, etc.

The Annual Growth of Trees.

The concentric markings found by cross section of the stems have long been relied upon to indicate the age of the plant, and the prevailing belief has been that the rings mark year growths. It appears that an observer in *Nature*, one of the foremost scientific publications, gives observations which would indicate that in some cases, at least, the rings do not represent year periods. During a visit to the ruins of Palenque, Mexico, in 1859, M. Charney caused all the trees that hid the facade of one of the pyramids of the palace to be cut down. On a second visit in 1880 he cut the trees that had grown since 1859, and he remarked that all of them had a number of concentric circles greatly superior to their age. The oldest could only have been 22 years of age, but on a section of one of them he found 250 circles. The tree was 60 to 65 centres in diameter. A shrub 18 months old at most had 18 concentric circles. M. Charnay found the case repeated in every species and in trees of all sizes. He concluded that in a hot and moist climate, where nature is never at rest, it may produce, not one circle a year, as with us, but one a month. The age of a monument has often been calculated from that of the trees that have grown on its ruins. For Palenque, M. Larainzar calculated 1,700 years, having counted 1,700 rings in a tree. M. Charnay's observation requires the number to be cut down to 150 or 200 years, making a considerable difference, 1,500 years.

Prof. Bachelart asks whether M. Charnay took account of certain colored rings which some tropical trees present in cross section, and which are to be distinguished from the annual circles. We have not yet seen any reply from M. Charney removing the doubt as to whether he made a correct discrimination between the colored rings and the annual rings, and therefore the subject is given as an interesting but still open question.

WINTER is the best season for prospecting in Garfield, Gillis mountain and most other mining districts in that direction in southern Nevada, as the snow obviates the necessity of packing water for long distances.

THE copper industry of Utah promises to become of much magnitude. New discoveries of copper ore are frequent in the southern portion of the Territory.

IMPORTANT SEMI-TROPIC COLONY ENTERPRISE.

The Fairest and Best of Colonies.

THE REDLANDS,

In San Bernardino County, California.

Superior Soil, Climate and Irrigating Improvements.

The following information concerning one of the best-reputed and promising colony enterprises in southern California, is from the Riverside *Press*, of San Bernardino county, April 1, 1882:

A Model Settlement.

No place in California has sprung into public notice so rapidly and gained so deserved a reputation in so short a time as has the new tract of Redlands.

This tract is located between Old San Bernardino and Crafton on the south side of Mill Creek ditch and comprises 2,500 acres of as choice fruit lands as can be found in the State. The land is of a reddish clayey loam, not clayey enough to work hard, having sufficient admixture of sand to hold moisture and give the best results when planted to orchard or vineyard. The red lands of the State are everywhere celebrated as being superior for tree and vine.

The tract slopes to the northwest and commands one of the grandest views to be found in the State. To the north and northwest lies stretched out, several hundred feet below, the San Bernardino valley, with the towns of San Bernardino and Colton plainly in view, while, looking to the westward at night, the headlights of the Eastern-bound trains can be distinctly seen for 40 miles. Beyond the San Bernardino valley to the northwest, and stretching around to the northeast, the chain of mountains tower 9,000 ft. above the sea level, culminating in Mount San Bernardino, 11,000 ft. high, and Grayback, 11,550 ft. high, both of which stand up boldly from the Redlands point of view, and whose tops are covered with snow more than half of each year. Around to the left of the picture are the Cucamonga peaks, 40 miles distant, which complete the semi-circular mountain chain that makes such a beautiful background to the landscape. For mountain and valley scenery no more beautiful location can be found in the State than Redlands, outside of Yosemite valley.

Redlands is located 10 miles from the county seat, the same distance from Colton, and 15 miles from Riverside. The track of the Southern Pacific railroad runs one and a half miles from the center of the Redlands tract, and a depot will be established at once for the accommodation of Redlands, Lugonia, Crafton and Old San Bernardino.

The Redlands tract is laid off by running avenues from northeast to southwest, one-quarter of a mile apart and cross streets at right angles to those avenues every half mile, thus cutting the tract into blocks, each of which contains 80 acres. The avenues are each 100 ft. wide. The cross streets are 60 ft. wide.

Although the first work done on the tract by settlers could not be commenced till about the 1st of January, 1882, there are at the present time some 10 or 12 houses erected and in process of erection, with several to commence work soon. A number of tracts, in addition to those on which houses are being built, are being plowed up and planted to orchard and vineyard.

The lateness in the season when the land was bought by purchasers, prevented many from getting their land set out to trees or vines this year, but all who have purchased are making arrangements to plant extensively next winter and spring.

Town Plat.

Near the center of the tract is a town plat, consisting of 140 acres, cut up into lots ranging from an ordinary business lot to two and a half and five acre residence lots.

The Water System.

Is one of the most perfect in the State. The water supply comes partially from the South Fork ditch of the Santa Ana river and partially from private water developments in the Santa Ana canyon and other localities. The waters are to be conducted to a large reservoir, located in a canyon adjoining the tract, and distributed from this reservoir by means of cement pipes. These pipes will be so laid as to carry the water without loss to the highest point on each ten-acre lot. The basis of water supply is one inch of water, statute measurement, to each eight acres of land. This is ample, and up to the best irrigated tracts in the State.

Work on the water system is being pushed as rapidly as men and money can do the work. The dam to the reservoir, which is ultimately to be 60 and perhaps 80 ft. high, is now about half done; the iron discharge pipes and watergates are in position, and nearly four miles of the largest distributing pipes are already manufactured, and most of this is laid. This portion of the work embraces the 8, 10, 12, and 14-inch pipes—the heaviest portion of the work. The smaller pipes, none of which will be less than four inches, will be made and laid as soon as the larger pipes are completed.

The orange, lemon, apricot, peach and raisin grape, will grow here to perfection.

Following is a list of the property owners at the present time. Those who have moved upon the tract are credited to Redlands, and the others to localities where they now reside:

Names.	Acres.
J. G. Cockshutt, Redlands	20
O. W. Kidder, Redlands	10
J. F. Welsh, Redlands	20
B. W. Brown, Redlands	10
Israel Beal, Redlands	10

W. A. Merriam	10
J. T. Ford, San Bernardino	20
T. S. Ingham, San Bernardino	10
L. Jacobs, San Bernardino	20
Total sold	1,004

Judson & Brown (San Bernardino, P. O.), owners of the tract, are energetic men, who leave no stone unturned to make their enterprise a success. They do not try to figure how little they can do and sell their land, but where they can put another thousand dollars and make the tract more desirable to first-class settlers. There is nothing shoddy about their operations. Redlands will stand in a few years as one of the finest settlements on the Pacific coast.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. **New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.**

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

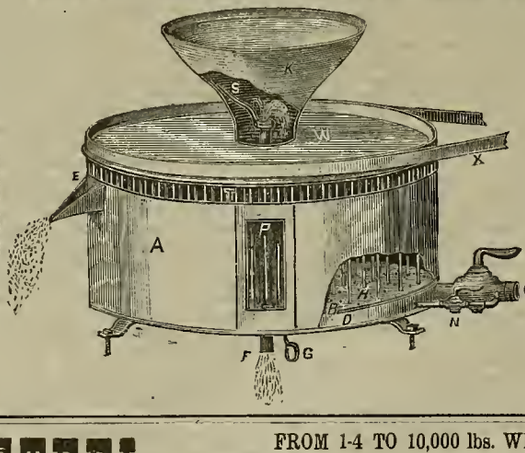
JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE RAPID ORE CONCENTRATOR.

Patented March 28, 1882, by G. A. METCALF, of Melden, Mass.

CHEAPEST AND BEST **CONCENTRATOR** In the Market.



For further Particulars address the Inventor.

HAS RECEIVED THE **COMMENDATION** Of the Best Judges.

COPP'S AMERICAN MINING CODE.

United States, State and Territorial Mining Laws, and Land Office Regulations; Digest of Land Office and Court Decisions; List of Patents Issued, and Dr. Raymond's Glossary, with Forms for Mechanics' Liens, Location Notices, etc.

Price, postpaid, in paper, 50 cts; in cloth, $1.25.

Sold by DEWEY & CO., S. F.

California Inventors Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 252 Market St., S. F. Elevator, 12 Front St.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequaled strength, toughness and durability.

An invaluable substitute for forgings or cast-iron requiring three-fold strength.

Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.

15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.

CRANK SHAFTS, SHOES, DIES and GEARING specialties.

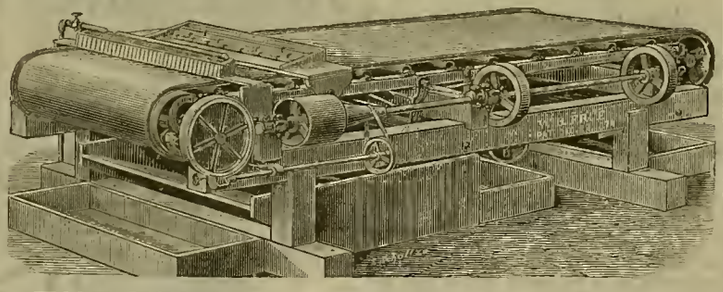
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hackley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES.

SAVE YOUR GOLD!

— BY USING —

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save more gold than any other method, and double the amount of the same surface of ordinary copper plates. The only plates that have proved durable and satisfactory.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

San Francisco Gold, Silver and Nickel Plating Works,

265,984—FAN WHEEL—Wm. Schmolz, S. F.

9,374—TRADE MARK—G. N. Miles, Stockton, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CLOTHES-DRYER.—James H. McCauua, Fresno City, Cal. No. 266,040. Dated October 17, 1882. This invention relates to certain improvements in that class of clothes-dryers in which a number of arms diverge from a supporting center to which they are hinged or joined, and have lines extending from one to the other. These arms have usually short braces pivoted to them and meeting midway, the whole being supported upon a central post. This invention consists of diverging arms, the lower ends of which are hinged to a hub which slides loosely upon a vertical post, and their upper ends are united by particularly-arranged parallel lines upon which the clothes are to be hung. A second hub or cross is fitted upon a pin upon the top of the post, and short arms extend from it upward and outward until they meet the longer arms, to which they are connected by links. The angle of these short arms is more obtuse than that of the longer arms, and as the center or hub of the longer arms slides loosely upon the post the weight is supported by the short arms and their hub, and they then operate to keep the outer arms extended, and the greater the weight of clothes upon the lines the tighter they will be stretched.

COMBINED SPOOL AND THIMBLE HOLDER AND THREAD CUTTER.—Antonio M. Barrett. Ione city, Amador county, Cal. No. 266,009. Dated Oct. 17, 1882. This invention relates to a new and useful device, which is called a "combined spool and thimble holder and thread-cutter." It consists of a suitable spindle or shaft for receiving the spool, of a standard for supporting the thimble, of a cutter for severing the thread, and of a hook or pin for affixing the device in convenient position. These are the results of a construction as follows: A single wire is bent to form a cross above and an open base below, one end of the wire fitting into a hook on the other end at one corner of the base and forming the spindle for the spool. Upon the front of the cross above is soldered a wire, the upper portion of which is bent outward and receives one end of a small blade extending from the main piece. Upon the back of the cross is affixed a bent pin or hook, which sustains the device, and forms with the top of the cross a secure resting place for the thimble.

DEVICE FOR OPERATING CABLE RAILWAY GRIP.—Albert Grutter. S. F. No. 266,029. Dated Oct. 17, 1882. This invention relates to an apparatus for operating the grips of cable railways, so that more power may be applied to close the grip when required. It consists of a hand wheel and a pinion, the shaft of which is journaled upon the ordinary operating lever, so that the pinion may engage with the teeth of a rack formed in the lower part of the arc upon which the lever travels, so that the power of the wheel and pinion may be applied whenever desired.

CAMERA ATTACHMENT.—Egertou R. Higgins. San Francisco, Cal. No. 266,035. Dated Oct. 17, 1882. This invention relates to certain improvements in photographic apparatus, and it consists in the employment of a musical or other audible attachment and a movable eyepiece, with means of setting them in motion, and in connection with these, of a shutter which may be subsequently opened by a pneumatic or other device, which also operates the eye-piece and the musical attachment.

SHEEP HOLDING DEVICE.—Clairessa B. Cook, San Francisco. No. 266,016. Dated Oct. 17, 1882. This device is principally useful for holding sheep while they are being sheared. It consists of standards having collars so hinged that they may be opened and clasped around the neck and hind legs of the animal, and thus hold it firmly while being operated upon. The animal is in a standing position and being held thus, is prevented from struggling while being sheared. It is intended to lessen the labor of the shearer.

The Penryn Granite Works.

These celebrated granite works are located at Penryn, Placer county, California, some 28 miles east from Sacramento, on the line of the Central Pacific Railroad. The first of the several quarries from which the stone is procured was opened in 1864 by the present proprietor, Mr. G. Griffith, whose establishment is perhaps the only complete one of its kind on this coast. His quarries cover some 680 acres at Penryn and Rocklin, the latter point being six or eight miles distant from the former in a due westerly direction.

The cutting and polishing works located near Penryn and the principal quarries, are very extensive and interesting institutions. They consist of various buildings and sheds filled with a vast amount of machinery employed in cutting and polishing the granite. Here 200 men find constant employment, and the force is frequently much greater.

Specimens of the several varieties of granite taken from Mr. Griffith's quarries exhibited at the Philadelphia Centennial exposition were pronounced by experts to be the best for all purposes of any produced in the United States. The chief superiority and predominating excellence of Penryn granite consists in the fact that it does not change color by exposure, and that it contains no iron, as does even the celebrated Quincy (Massachusetts) granite, heretofore supposed to be the best granite found in this country. These advantages give to the Penryn granite a vast superiority when used for monuments, tombstones, or when placed in any position where it will be constantly exposed to the elements. The predominating shades of Penryn granite are blue, grey and black, the last-named very much resembling the celebrated black granite found in Egypt, and exceedingly beautiful when highly polished.

The granite used in the construction of the State House at Sacramento was furnished by Mr. Griffiths, and the number of public and private structures in this city ornamented with Penryn granite is so large that their very multiplicity precludes individual mention of the same.

Mr. Griffith is one of California's truly progressive and enterprising mountain business men. He is constantly developing new quarries and increasing his already gigantic enterprise. He is the head center of the large community of artisans over which he presides, and possesses the esteem and respect of its members.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED O. HOAG—California.
L. L. WOODMANSEE—Nevada State.
E. W. CROWELL—Los Angeles county.
L. WALKER—Butte, Tehama and Shasta counties.

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,
No. 252 Market St., S. F.

Putnam House for Sale.

Most persons resident on this coast who have traveled along the main line of the Central Pacific railroad are aware of the fact that the Putnam house, at Auburn, Placer county, is one of the largest and most elaborately furnished hotels to be found anywhere in the interior. An advertisement in another column of this paper announces the fact that it is offered for sale.

To Engineers and Draftsmen.

WANTED.—A good wood engraver. Also, a draftsman, who can make pen and ink drawing on paper or stone. Apply at this office.

Old Papers Wanted.

Twenty cents each will be paid for a limited number of copies of any of the following Nos. of the MINING AND SCIENTIFIC PRESS, if received soon at this office: No. 1, of Vol. 13, 1866; No. 5, Vol. 18, 1869; Nos. 1 and 26, of Vol. 20, 1870; No. 1, of Vol. 22, 1871. Also, 10 cents per copy for Nos. 2, 3, 4, 7, 10, 11, 12, 13 and 15, of Vol. 30, 1875. If any one who has files of back volumes of the PRESS, which they may like to dispose of at a moderate rate, will send us a memorandum of the same and the price, we may be able, sooner or later, to assist in their disposal.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent solicitin business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their agency from week to week and year to year.

Rooms and Board in Oakland.

Rooms (with or without board) can be had in Oakland on reasonable terms, with a family of English people, location, a pleasant one within 3 blocks of Postoffice. Good references furnished and required. Call or address No. 1274 Franklin St., Oakland, or enquire at the office of this paper.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequaled by any other published embracing the subjects treated. Post-paid, $7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. A valuable and carefully written work. Postpaid, $3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by Dewey & Co., S. F.

Mining and Other Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Land Purchasers' Association.—Location of principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors or Trustees, held on the 3d day of October, 1882, an assessment of Four Dollars ($4.00) per share (being a part of the 44th installment on the subscription to the stock) was levied upon the capital stock of this corporation, payable immediately to the Secretary at 318 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on MONDAY, the Thirteenth (13th) day of November, 1882, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on WEDNESDAY, the THIRTEENTH (13th) day of DECEMBER, 1882, to pay the delinquent assessments, together with the cost of advertising and expenses of sale.

C. S. WRIGHT, Sec'y.

OFFICE—318 Montgomery street, San Francisco, California.

N. B.—This assessment is to pay the taxes on the property of the Association for the current year.

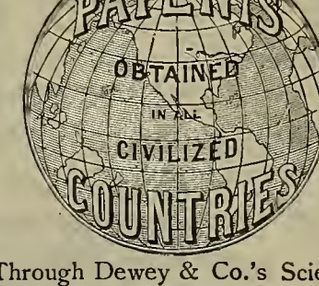
The best of



Through Dewey & Co.'s Scientific Press Patent Agency.
No. 252 Market Street. Elevator, 12 Front St., S. F.
Telephone No 858.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

THE PUTNAM HOTEL AND lot, in the town of Auburn, Placer county. The house is a large three-story building, new, and contains 60 rooms. It is in first-class condition, with all modern improvements, and is doing a fine business. It is furnished throughout with the best furniture. Persons who contemplate engaging in the hotel business will find this a rare opportunity, as the property is good and in a thriving town. Bids for the property will be received in writing by the executor of the estate, ADDISON PUTNAM, or by J. T. KINKADE, his attorney, at Auburn, Cal.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for Instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are Infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3. This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates rehlasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50 % to 60 % stronger than the strongest Nitro Glycerine Compound and impervious to wate. Even hot water does not diminish its strength. We are now introducing the same.

Colorado Iron Works,

MANUFACTURERS OF

ENGINES, BOILERS, RAILWAY CAST AND WROUGHT WORK, BRIDGE WORK, BOLTS AND BOLT ENDS, BUILDING WORK, ETC.

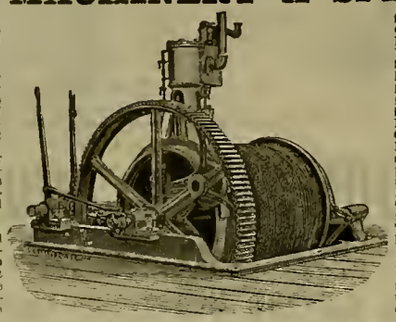
MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the



following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupellation Furnaces, Market Kettles, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

TRY ONE PAIR AND BE CONVINCED.

F. H. WILSON, 232 West Baltimore St., Baltimore, Md.

WATER JACKET SMELTING FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN SIXTY of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to examine mines and to superintend construction and running of furnaces. Estimates given upon application.

Send for circular.

RANKIN, BRAYTON & CO.

Pacific Iron Works, San Francisco.

Carson and Colorado Railroad.

(NARROW-GAUGE.)

The Company announces the completion of its line March 1, 1882, to OANDELARIA, Columbus Mining District, Esmeralda Co., Nev., 178 miles from Mound House (Junction with Virginia and Truckee Railroad).

STAGE CONNECTIONS,

At Hawthorne with U. S. Stage Company's daily coaches for Aurora (20 m.); Bodie (37 m.); Lundy and Bridgeport.

At Lunday (125 miles from Mound House) with Gilmer, Salisbury & Co.'s tri-weekly stages (leaving Tuesday, Thursday and Saturday mornings) for Grantsville, Belmont and Tybo.

At Belleville (150 miles from Mound House) with Belleville and Independence Stage Co.'s stages for Benton (40 m.), Bishop Creek, Big Pine and Independence.

At Candelaria, with U. S. Stage Co.'s stages for Columbus (8 m.), Silver Peak, Montezuma, Alida Valley, Gold Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento Reno, Carson and Virginia R. R. Ticket offices.

This is the direct and natural route for Passengers and Freight, to points in Southern Nevada, Mono and Inyo counties, California. The line, laid with steel rails and redwood ties and equipped with new and first-class rolling stock, is penetrating new and most promising Mining Districts which are now attracting deserved attention throughout the country.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

NATIONAL COMPRESSORS and ROCK DRILLS.

EDWARD A. RIX, Agent,

Successor to **REYNOLDS & RIX,**

No. 49 Fremont Street, San Francisco, Cal.

MANUFACTURERS OF AND DEALERS IN

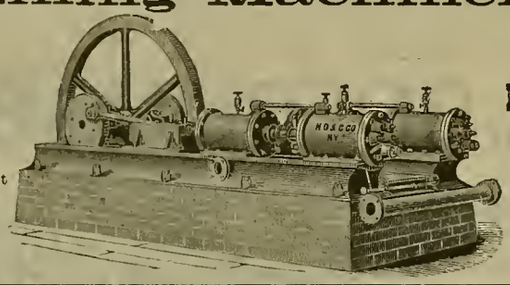
Mining Machinery.

We manufacture the

BEST

Air Compressors

Ever driven by belt from Water Power.



Hoisting Rigs.

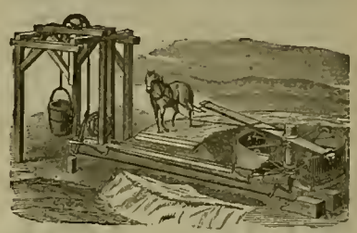
DONKEY ENGINES

For Pile Driving.

MINING CARS,

Ore and Water

BUCKETS.



MINERS' HORSE-WHIM.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

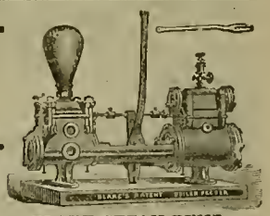
PACIFIC MACHINERY DEPOT.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

H. P. GREGORY & CO.,

Importers and Dealers in Machinery and Supplies.

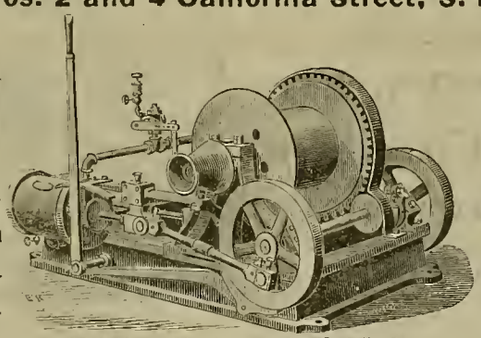
Nos. 2 and 4 California Street, S. F.



BLAKE STEAM PUMP.
More Than 16,000 in Use.

SOLE AGENTS FOR.

- Fay & Co., Wood Working Machinery.
- Bement & Sow's Machinists Tools.
- Blake's Steam Pumps.
- Perry's Centrifugal Pumps.
- Gould's Hand & Power Pumps.
- Perrin's Band Saw Blades.
- Payne's Vertical and Horizontal Steam Engines.
- Williamson Bros. Hoisting Engines.
- New Haven Machine Co.'s Machinists' Tools.
- Otte Silent Gas Engines.

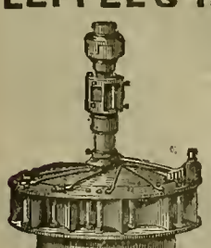


Hoisting Engines of all Kinds.

SOLE AGENTS FOR.

- Sturtevant's Blowers and Exhausts.
- Judson's Steam Governors.
- Pickering's Steam Governors.
- Tanite Co. Emery Wheels.
- Nathan & Dreyfus' Oilers.
- Korting's Injectors and Ejectors.
- Disston's Circular Saws.
- New York Belting & Packing Co.'s Rubber Belting, Hose, Packing, etc.
- Ballard's Oak Tanned Leather Belting.

LEFFEL'S IMPROVED WATER WHEEL.



PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for **New Prices,** before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,
and 110 Liberty St., N. Y. City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

READY FOR DELIVERY.

LATHES, DRILLING MACHINES, PLANING MACHINES

and Other Machine Tools,

STRONG, DURABLE AND SUPERIOR TO IMPORTED MACHINES.

Wheel Cutting to Order.

SAN FRANCISCO TOOL CO., - - 21 Stevenson St., S. F.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

RICHARD C. REMMEY, Agent,

Philadelphia Chemical Stoneware Manufactory,

On O E Cumberland St., Philadelphia, Pa.

Manufacturer of all kinds of Chemical Stone Ware for Manufacturing Chemists. Also, Chemical Bricks for Glove Towers.

California Wire Works,
(Successors to A. S HALLIDIE,)
6 California St., San Francisco.

WIRE ROPES AND CABLES,

Manufactured at our works, guaranteed to be equal in quality to any made, and as cheap, for

MINING AND SHIPPING PURPOSES, ETC.

Wire Suspension Bridges and Aqueducts.

WIRE TRAMWAYS **WIRE ROPE** CABLE RAILWAYS.
FLAT AND ROUND
WIRE
GALVANIZED & PLAIN

California Wire Works,
(Successors to A. S. HALLIDIE),
6 California St., San Francisco.

WIRE OF ALL KINDS,

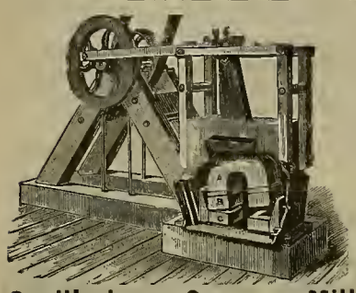
Manufactured at our Wire Mills in this city, superior to any imported, for

Telegraph, Bailing and Fencing, etc.

WIRE STAPLES AND WIRE NAILS.

Wholesale and for Export.

MILL AND MINING MACHINERY.



Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

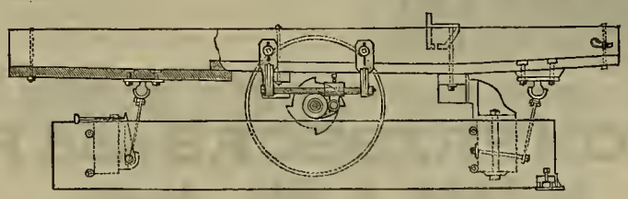
Manufactured by
F. A. HUNTINGTON, 220 Fremont St., S. F., Cal. | FRASER & CHALMERS, 145 Fulton St., Chicago, Ill.

Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
220 Fremont Street, San Francisco, Cal.

F. A. HUNTINGTON,

No. 220 Fremont Street, - - San Francisco, Cal.

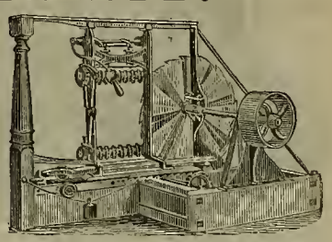


PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.



SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

F. A. HUNTINGTON,
No. 220 Fremont Street, San Francisco.

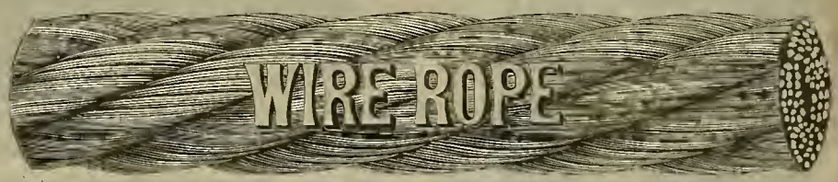
THE JOHN A. ROEBLING'S SONS CO.,

Manufacturers of

WIRE ROPE and WIRE

Of Every Description.

For Inclined Planes, Standing Ship Rigging, Suspension Bridges, Ferries, for Mines and all kinds of Heavy Hoisting; for Stays and Guys on Derricks, Cranes and Shears; for Tillers, Sawmills, Sash Cords, Lightning Conductors, etc.
Galvanized and Plain Telegraph Wire.



THE BUCK THORN BARBED FENCE (One Piece Solid Steel)

Agents for **NEW JERSEY WIRE CLOTH CO.,**

14 Drumm Street, - - SAN FRANCISCO, CAL.

SEND FOR CIRCULAR.

PACIFIC BANK
Established 1863.
Capital Stock $1,000,000.00
Surplus 460,800.70

San Francisco, Cal., July 1, 1882.

We take pleasure in presenting for your consideration the following Thirty-eighth Semi-Annual Statement of the condition of this Bank:

RESOURCES.

Bank Premises	$150,000 00
Other Real Estate	12,825 35
United States Bonds	629,507 60
Land Association Stock	15,121 55
Loans and Discounts	1,785,000 20
Due from Banks	527,279 09
Money on hand	632,365 30
	$3,752,099 09

LIABILITIES.

Capital paid up	$1,000,000 00
Surplus	460,800 70
Due Depositors	1,953,672 80
Due Banks	337,491 09
Dividends unpaid	134 50
	$3,752,099 09

This Bank has special facilities for doing all kinds of banking business.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

FIGARI & RICHMOND'S
BOILER AND TUBE COMPOUND.

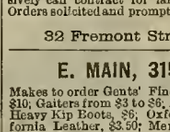
We **guarantee** our **COMPOUND** to remove all scale and **prevent** any more being deposited. The **COMPOUND** forming a glazed surface on the iron, to which no scale will adhere and which preserves the iron.

The preparation is strictly **vegetable**, and is **warranted** to do all that is claimed for it without injury to the metal. Send for a circular.

H. P. GREGORY & CO., Agents,
San Francisco.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,



Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

E. MAIN, 315 Folsom Street,

Makes to order Gents' Fine French Calf Boots from $6 to $10; Gaiters from $3 to $6, Alexis from $3.50 to $5; Mens' Heavy Kip Boots, $6; Oxford Ties, French Calf, $4; California Leather, $3.50; Men's Working Shoes from $2.50 to $3; Children's Shoes made to order. Persons in the country ordering to the amount of $12, I pay the express charges. I sell nothing but my own manufacture.

VOLUME XLV Number 19

Health and Underground Work.

One of the most prominent conditions of a miner's working life, certainly the first to be noticed by the casual visitor, is the absence of sunlight, a very deleterious condition as many physicians and engineers of large practical experience consider it, while others positively deny that it has any injurious effect. Dr. J. T. Carpentor, of Pottsville, in a paper read before the Schuylkill County, (Penn.) Medical Society, says that deprivation of sunlight must be a very strongly predisposing cause of disease. It is to be expected that the result of this deprivation will become apparent in general anæmia, in chronic nervous irritations, in tendencies (easily to be developed by exciting causes) toward scrofula, tubercular phthisis and allied maladies. Other practitioners, however, assert that the deprivation of sunlight is among the least of the miner's afflictions; that no injurious effects from it are perceptible, and that no acute disease can be traced either wholly or in part to this cause; while physicians will probably continue to differ forever as to whether or not absence from sunlight during all the working hours predisposes to or prolongs any chronic complaint. In this connection it must be born in mind that the miner's work is carried on wholly by artificial light, and that usually of a very poor quality. Not the faintest ray of sunlight can penetrate to him, and about the first thing the unaccustomed visitor usually remarks is that it is so *very* dark. It needs but a slight exercise of the imagination to persuade him that he has at last found a sample of that thick darkness that might be felt, which once visited the land of Egypt.

In the winter season, especially when the mines are working full time, their inmates, as a rule, see but little of the sun during their working days. They enter the mine before sunrise, and quit it after sunset. It is, however, a very common practice among them to work week about, one week by day and the next by night. In this case they have at least from four to six hours of every day's daylight during their night week, and in any case they generally spend Sunday above ground. They do not complain of want of sunshine, and it is difficult to trace any ill effects of its absence upon them. Their complexions are pale, but not more so than those of persons who work at night or in shaded rooms above ground, and their eyesight, as a general thing, considering the miserable light they have to work by, is remarkably good. Few miners are compelled to wear eye glasses for either working or reading, before reaching old age.

Concentration of Ores.

The failure on the part of so many improved "processes" based on the use of chemical reagents which seemed to possess good results in the working of "rebellious" ores, has more or less discouraged people from investing in mines with that kind of ore. While in many cases these ores are worked at the mine, yet after years of costly experiment the balance sheet of profit and loss in the treatment of low-grade and rebellious ores too often shows the balance on the wrong side of the account.

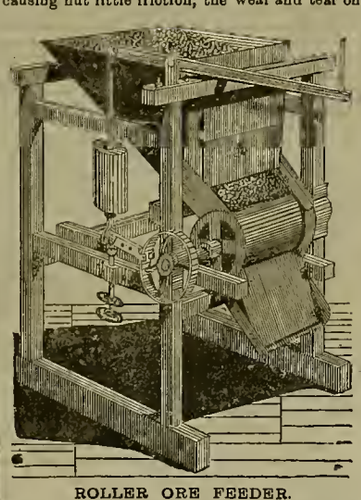
We have numbers of low-grade mines holding vast treasure, only waiting for the successful "process" to be developed. The question is continually before us, how can we make these base metal mines profitable?

The most feasible plan seems to be concentration. Relieve the ore of a large percentage of the gangue until what is left is rich enough to pay a profit on working or transportation. Of course this implies an ability to concentrate cheaply. With the improved machinery now available this can in many places be done with great benefit. We feel certain that many mines now idle would be started up at a profit should the owners investigate thoroughly the question of concentration. With reduction works at so many points now it would seem as if hundreds of these low-grade mines could be worked at a profit.

The Roller Ore Feeder.

On this page we give an illustration of the roller ore feeder patented May 28, 1882, showing its construction and general arrangement. The roller which delivers the ore to the battery is placed at the month of the chute leading from the hopper, to which it acts as a gate. When the roller is at rest the ore remains in the chute, but on its slightest forward movement a portion of the ore is fed into the battery. The chute is constructed to deliver the ore on the top of the roller in a manner analagons to the way water is applied to an overshot water-wheel, and if the flow of ore were constant the roller would be rotated by it as the water-wheel is driven by water. Or, as a mill-owner remarked who has them in his mill, "the ore passes over the roller as easy as falling off a log." Owing to the slight movement of the roller required to deliver the ore, a very small amount of power is required—not detracting from the efficiency of the stamp that operates it in any perceptable degree.

As the amount of power consumed is small, causing but little friction, the wear and tear on



ROLLER ORE FEEDER.

the machine are merely nominal, and rendering it very durable.

The hopper is provided with a gate to regulate the passage of the ore according to the varying requirements of different kinds; coarse ore requiring a higher gate than dry ore of a finer grain.

The clutch which operates the roller has an adjustment by which the length of its throw can be made longer or shorter according to the nature of the ore; dry requiring a shorter throw than ore that is wet and adhesive.

There is also another adjustment for the same purpose, operated by the hand wheels, which can be used when the machine is in full operation.

In front of the roller is an apron or scraper, and in case the ore contains clay which adheres to the roller, the scraper clears it and causes the clay to fall into the battery.

As ordinarily constructed, the length of the roller is sufficiently long to feed the ore under three stamps. But the length may be extended so as to feed under all of the stamps in the battery, even if there should be six or eight. Or by changing the form of the apron in front, the ore may all be fed under one stamp.

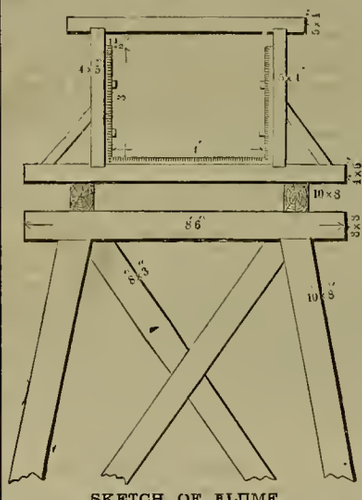
This feeder is in use in the Keystone mill, in Amador county, Cal., and the Bunker Hill mill at this same place, where it has been in operation for two years, giving perfect satisfaction, never having been out of order or costing a dollar for repairs. This feeder can be seen at the Golden State and Miners' Iron Works, 237 First street, in this city.

Measures for the relief of sufferers by the cyclone in Vuelta Abajo region, Cuba, continue.

Flumes and their Construction.

In crossing ravines in this State, flumes, or wrought iron pipes are used. Many miners object to flumes on account of their continual cost and danger of destruction by fire. Where used and practicable, they are set on heavier grades than ditches, 30 to 35 ft. per mile, and, consequently, are proportionately of smaller area than the ditches. In their construction a straight line is the most desirable. Curves, where required, should be carefully set, so that the flume may discharge its maximum quantity. Many ditches in California have miles of fluming. The annexed sketch drawn by A. J. Bowie, Jr., will show the ordinary style of construction.

The planking ordinarily used is of heart sugar pine, one and a half to two inches thick, and 12 to 18 inches wide. Where the boards join, pine battens three inches wide by one and a half thick cover the seam. Sills, posts and caps support and strengthen the flume every four feet. The posts are mortised into the caps and sills. The sills extend about 20 inches beyond the posts, and to them side braces are nailed to



SKETCH OF FLUME.

strengthen the structure. This extension of the sill timbers affords a place for the accumulation of snow and ice, and in the mountains such accumulations frequently break them off, and occasionally destroy a flume.

To avoid damage from slides, snow and wind storms, the flumes are set in as close as possible to the bank, and rest, wholly or partially, on a solid bed, as the general topography and costs will admit. Stringers running the entire length of the flume are placed beneath the sills just outside of the posts. They are not absolutely necessary, but in point of economy are most valuable, as they preserve the timbers. As occasion may demand the flume is trestled, the main supports being placed every eight feet. The scantling and struts used are in accordance with the requirements of the work.

THREE 20-stamp quartz mills have been purchased for Atlanta, Idaho, and will be shipped next summer. One is for the Leonora mine, one for the Atalanta and the other for the Tehama. Twenty-five thousand dollars have been authorized by the mining companies there for the purpose of digging a wagon road down Boise river from Atlanta to Boise.

THE Victoria district, in which George Hearst is operating extensively, is a few miles from Gage station in New Mexico, and abounds in carbonates similar to those which have made the Leadville district so famous.

THE imports of copper into England from January 1st to September 30, equal 68,885 tons, valued at £4,311,089.

Miners' Grievances.

The mining community of Great Britain is by no means passive under what it considers injustice to it as a class. When obnoxious measures are enacted by Parliament, the miners let Parliament know that the measures are obnoxious and not only this, but they as a class suggest to that august body what legislation should be carried out. Other working classes, represented by trades unions, do the same thing for their respective trades. This is illustrated by the demands of the recent Conference of Miners and Trades Union Congress, held in England. Each of these bodies suggested to Parliament certain reforms they expect to make for their benefit.

Looking at the demands made from this distance, it seems as if the miners and the workmen did not have much faith in their employers doing for them what should be done. And this doubt takes the direction of providing for more perfect safety to employees. It appears to be considered essential to the safety of miners and those engaged in factories and workshops that there shall be a staff of sub-inspectors, who shall periodically examine every mine in the kingdom, and these are to be drawn from persons ordinarily engaged in mining pursuits, whilst there is to be an army of inspectors of factories and workshops who are to be taken from those following different handicrafts. Of these latter, one of the speakers estimated that not less than 500 should be appointed to do the work required in a satisfactory manner. As to sub-inspectors of mines, probably 200 would be considered sufficient as a commencement.

Another grievance which the miners have discovered is that the underground managers and foremen are not sufficiently educated, so that it is proposed that they shall undergo an examination and have certificates the same as the chief manager. Those in charge of boilers are also to be men who practically understand them, whilst fire-triers are to make their rounds in a different manner to what they have hitherto done. No more powder is to be used for blasting, which is to be superseded by the lime cartridges. Check-weighmen are to have more liberty than hitherto. The workings in all mines are to be frequently visited by the sub-inspectors without any previous notice being given, so that less responsibility will fall upon the managers, for it will be divided between them and the sub-inspectors, whose only qualification is to be that they are practical miners. No man is to be allowed to contract himself out the Employers' Liability Act. There are to be more members of Parliament connected with mining and other industries, and it was stated that a subscription of 1d. per week from the men who are represented at the Congress would raise £25,000, which would be sufficient payment for 25 members to represent the constituent of the Congress.

Although some of the demands made may appear to be radical in their nature, and to savor of "Unionism," it seems as if most of them were no more than should be complied with. If the enforced presence of inspectors will slightly increase the cost of coal getting, it will greatly increase the safety of the mine—which is more important to the working miners. If they consider it a greivance that unskilled and uneducated men have charge of boilers, and that foremen and underground managers should be suitably educated and instructed, the grievance should be remedied. There is nothing at all unreasonable in this. If mine owners employ unsuitable persons for positions of responsibility, the men themselves whose lives are endangered are perfectly right in demanding a change.

To see demands of this sort made in a formal manner by representatives of so large a class as the miners of Great Britain is an evidence that they appreciate the advantage of education and knowledge. They do not wish to trust themselves to the care of people who are not properly instructed. Parliamentary commission will, no doubt, look up the matter complained of, and will see that plain defects on the mining laws are remedied.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Mining at Ellsworth, Nevada.

Geological Formation and Mineral Veins.

EDITORS PRESS:—I take upon myself, in this communication, the discussion of practical questions relating to mining, and shall confine myself chiefly to this district (in which I am now resident) and its surroundings. It will be necessary in the first place, in order to convey correct ideas of what I wish to advance, to prefaces my remarks with an outline of the mineralogical character of the district and its metaliferous accompaniments. That both the mineralogical and metaliferous character of a district are affected by its geological formation and constitution, will be readily understood. Mining, in the general acceptation of the term, respects metalifsrous minsrals and other subterranean products. It is, therefore, a pursuit with reference to objects more or less outlined and defined; and as they induce the operations which are generally of a more or less extensive kind, too much care cannot be taken in ascertaining their character and quality.

The conditions above named are essential to successful mining, but when existing do not always insure it, as incompetent management and direction in the mode and manner of the operation is frequently found more than a counterpoise to such a valuable, and, when understood, highly appreciable combination.

The district contains

All the Elements of Success.

Geologically, it is the miner's beau-ideal, bedded by a basaltic ridge constituting the axis of the mountain, and flanked by a porphyritic granite of an easy and peculiar character. In this granite the principal mines are situate, in groups, baving, figuratively speaking, family relations. The misfortune has been that in times past no attention was paid to this relationship or any regard to the requirements of mining as an industrial and remunerative commercial pursuit, and the consequence was that the natural grouping of lodes was ruthlessly disregarded and its provision violated, to the injury of the individual interest and to mining in general.

It is only in special instances that a single lode constitutes a prolific and lucrative mine, and hence the confraternity of veins, parallel, oblique and transverse, is held as a condition essentially paramount to the success of individual enterprise.

There is no peculiarity in respect to the mines of this district, except it be their distinctively indicative character of abounding wealth in depth. If conduct is the prelude of character, or, *vice versa*, character the prelude of conduct; or, in other words, if analogy is applicable to mining in its experimental relations and indicative conclusions, then natural indications of the wealth of this district is unsurpassed and indisputable. Take an instance, which is one in its truest signification: The bed, or containing rock, is, as I have already stated, porphyritic-granite of an easy fragile and pulveraent nature. The gangue associations of the lodes, or rather of the silver ones, is quartz, which, as is well known, is superior in hardness to the other ingredients of even formation, or any other granite, and therefore is more free to the action of elements which are not chemically elementary—such as rain, frost, atmospheric air, etc—to which the surface of almost all countries are exposed. An old and trite saying is that "the weaker goes to the wall," which means, in this connection, that the less compact of material substances yield more readily to external influences. Such must inevitably be the case between an almost simple mineral and an approximately agglomerated or abraised one.

The Phenomena of Such Indications

In this district are that the country rock disintegrates, and is warm and washed down into the adjacent valleys, whilst the harder and more compact material, of which the lodes are composed, resisting the action of such influences, whether chemical or mechanical, are found protruding above the surface—in some instances for considerable distances—displaying their character, and unmistakably indicating their wealth. The family relationship of veins is nowhere more pronounced than in this district, nor their confraternity more favorable. Reciprocity appears to be, if not an order of nature, an integral principle in her operations. In other words, her *modus operandi* is one of exchange, not exacting, never exhausting; give and take—or take and give, is the unmistakable expression of all her acts. Her economy in the mineral kingdom is wide-spread, elaborate and perfect. The cycle of her events in this realm is unmeasured by ascertained time, but its revolutions are as certain as are those of the orbs of heaven.

But enough of this. I have diverged from my subject, which was and is the mines of this district, and to them I will now return. But the profundity of nature, although infinitely beyond my comprehension, ever attract me, and I follow them. If philosophy is a factor in any event, in the prosecution of useful purposes and the attainment of beneficial results, it is in that of mining—to be and not to be—are extremes, antipodes which cannot be reached, the limit of the former is appreciable, but of the latter unattainable. Metaliferous lodes had a beginning. From whence did they originate? I will not go into the question further than to say, from an order in nature peculiar to themselves, they were not formed in a day, unless a day is an epoch in nature's indicator of time. We have to do with the sensible and realistic, with what is tangible and within the compass of reason, and the origin and formation of metaliferous minerals are included in this arena. If we have a correct idea from where they originate, we have also a comparative and general idea of what they amount to in quantity and quality. As is the nature of the soil to the seed sown in it, so is the nature of the rock formation of a district to the lodes or veins which traverse it. In this district, as I have already stated, its geological formation is faultless, its lodes situate in the most fertile of rocks and dipping towards the axis of the adjacent mountains, the cleavage of the rock being opposite to the dip of the lodes, the size, composition and general character of which are such as is always most highly approved where existing, and where absent most ardently desired. They exist here in most admirable conformity. The grouping, when pointed out to even an unexperienced observer, is to him clearly intelligible and satisfactory; but to one whose experience comprises a knowledge of the effects and results of such characteristics and such conditions, the aspect is wholly inspiring, confidence-elevating. It is only necessary to ensure from such sources abundant and continued success to obtain concessions in conformity with the general groupings, and then apply the proper methods for these developments.

The Ores

Are principally sulphides of silver, and the lodes commence to display their remunerative wealth at about 200 ft. below the surface, from whence onward in depth their career of prosperity is most marked and assured. The oblique and counter lodes drop in and conjoin in succession, and at every such event magnificently enrich the main trunk lodes. They are mines for miners who understand their professional business, and for capitalists who are desirous or content to develop the wealth, which shall handsomely repay them for their outlay and gratifyingly reward them for the judgment they exercise. I know of such properties, some of which can be had for a moderate proportion of the fully paid up capital stock of the company, the parties owning them not having the means to properly work them, but having the fullest confidence in the wealth they will yield, on development under competent direction and management are not only content, but desirous to transfer them to qualified companies free of expense for a share of the profits, which they feel assured would amply satisfy them. Such, it appears to me, is the proper course to adopt under such circumstances. The vendors of valuable concessions, when unable to develope the indicated wealth they have discovered, should be content to share the risks and the profits with those who provide the means for doing so. It is a species of co-operation, which should be more generally observed and practiced in mining. Capitalists would then have the satisfaction of knowing that the funds they provided would under judicious control be applied to useful and beneficial purposes. Fifty thousand pounds expended in the way I have stated, and on properties I can state, would in 10 years, I have no doubt, net fifty times that amount and early commence their respective careers of prosperity.

ROBT. KNAPP.

Ellsworth, Nye Co., Nevada, Oct. 18, 1882.

A Successful Prescription.

About a year ago, Prof. Hilgard received from the neighborhood of Anderson, Shasta county, a sample of red clay soil from the foothills of that region, with the following statement regarding its behavior under cultivation, from Mr. George H. Moore:

I have been here 10 months and raised about one and a half tons of hay on six acres, and potatoes at the rate of about one-tenth the bulk planted, etc. There is a dense thicket of chaparral and poison oaks, with some oaks and other brush. Not raising anything the past season has nearly crushed me, and one more year of all work and no pay will leave me too poor to move away. This is a very peculiar land, there being such a compact mass of clay and gravel cement composition, about four feet from the surface, that water does not penetrate below 15 in. from the surface.

The soil, of which a sample was sent, appeared to be quite similar to others from the foothills that have proved highly productive, and whose composition, as ascertained by analysis, showed good reason therefor. The analysis of the Anderson soil proved, however, that while fairly supplied with other ingredients of plant food, it is remarkably deficient in phosphates. Mr. Moore was so informed, and advised to apply to his land light dressings (200 lbs. per acre) of bone-meal, such as manufactured at San Francisco. The result of this treatment is given in the following note, lately received by Prof. Hilgard:

I got bone-meal last winter and used it as you so kindly directed. The barley did well, coming up and growing steadily until it reached its hight, producing well-filled heads of good length. Please accept my gratitude.

This looks like a tangible result from the application of science to agricultural practice. It appears from other samples received that this red clay chaparral soil is of quite extended occurrence in northern California, so that this demonstration of its only defect and its efficacious remedy is of more than local interest.

Forest Trees of California.*

The Great Sugar Pine.

(*Pinus Lambertiana.*)

"Beneath the forest's skirt I rest—
Whose branching pines rise dark and high,
And hear the breezes of the west
Among the threaded foliage sigh."—*Bryant.*

One of the most magnificent pines the world ever saw is the Great Sugar Pine of California! From 150 to 300 ft. high, 10 to 15 ft. in diameter, the body remarkably elegant and even of surface; for the fine water-line ramæ only serve to smooth and soften the neutral tint hark of this tallest priestly pine; and what a wonderful column! perfectly cylindrical, clean of branch or knot for hundreds of feet—usually two-thirds of the total hight—as it stands conspicuously in the midst of the forest, denizened among other wildwoods, yet exalted above them; and high up over all his kindred pines, in some remote degree, like the lofty palm tree of the tropics. Among the trees, a mountaineer of the most decided and commanding character, his top in sylvan glory and radiating its open but exceedingly long arms, widely spread afar towards the horizon, oft as one vast long bow at ease, upwardly curving, exhilerant and free; and yet they are neither naked nor lank in the best types, but side-plumed and grandly fringed by relatively short, lateral, and successively diminishing branches and branchlets to their main extremity's end, whence pend from one to three, or even five, very long cones tasseling their tips, from one to one and one-half feet long and three to five inches in diameter, suspended by stems four to five inches long; color of cone light cinnamon-brown or ripe-yellowish; thinnish scales loosely overlapped, oblong fan-form, without prickles, etc.; seeds oval, a little compressed, lines long, wings widest below the middle, obtuse; cotyledons, 13 to 15.

These long horizontal limbs may depend somewhat, more or less in old age, like the bow still on its back, not altogether unstrung, but they are never massed nor at all crowded, but always open so as to allow the wind—of the prominent storm-exposed head—free passage through, or, in extreme cases, only bending them leeward almost double, like a true Damascus blade—hilt to point. This remarkable length of limb, so tolerant of the tempest and vigor of recoil with returning calm; or, in other words, toughened strength with elasticity, is quite characteristic.

The wild red man of the wood is quick to perceive and apt to apply this and similar knowledge to the science of his own use, for no sooner does the harvest of the coveted *pinon* arrive, than ape-like, he climbs and clambers out astride the branch, and, teetering to the required sway, when, with a short timely jerk, the heavy cones are snapped off. The great use of the seed as Indian food we omit.

The rich dark plumes of vigorous blue-green foliage very much resemble the beautiful white pine of the East (*P. strobus*), especially when young—at length all further resemblance of form ceases. The needle-like leaf-straws are rather short, and somewhat twisted in age, from three to five inches long, very finely toothed on their edges, five in each tiny bootee, which is at length shed off like the white pins; these little bundles, in most cone-bearers, are more manifestly inserted in spiral order around the ultimate twigs.

The timber is not quite so soft, light and white as the white pine itself, but closely resembles it, and is alike in use and value, and, in some respects, superior, as it combines greater strength with elasticity.

Where the surface is burned the oozing sap concretes into a white manna-like sugar, sometimes nearly as crystalline and pure as refined loaf sugar, very sweet, with scarcely an appreciable pine-resin flavor; hence the common name sugar pine. If this could be obtained in quantity, its laxative and balsamic properties, apart from the palatable and nutritive, would highly commend itself to the attention of the medical profession. For obvious reasons, we cannot here, in all freedom, urge upon the public or the landscape artist the full claims of this expressive tree. To the bald scientific or the mere lucre-loving plod, any esthetic estimation of arboreal nature whatever might be deemed too poetic, imaginative, discursive, fanciful, or what not; briefly, irrelevant to the subject in hand. And what if we own no property in that royal realm, why should we be indifferent? And even our aversion may be suppressed. Is it not one of those occasions for tolerance and charity, and all the renowned and universal virtues among men? With due deference, therefore, to these varied tastes, always to be anticipated, we frankly confess our great surprise that even some few are found disparaging this noble pine on account of its open-hearted port, nor in our fascinated simplicity did it ever occur that the lack of foliage was a defect in this unique type of trees, being in no way amenable to any gross, massive or tumuloid standard of judgment. Set it down, then, to our fault, that we have no preconceived, abstract, and arbitrary notion of propriety for all the trees; that we do not even bow down and worship the almighty *Sixteen!* Perchance the peculiar charms of this tree in our eye may, to some extent, be borrowed from the striking contrast with other associated trees, for it is rarely in forests of its own, being mostly interspersed in all the Alpine, and some of the subalpine regions of the coast. To our taste, the great sugar pine hath the far-extended oratorical gesture and open magnanimous spread from the breast and top of a tall and representative, or corresponding type of some sacred benediction of "good will towards men," for trees always display in their bearings types of human attributes.

On the tablelands of middle Yuba a fair sample of a grove may be seen; indeed, almost anywhere in the common belt of about 6,300 to 7,000 ft. altitude, always excepting that peculiar medium coast-tempered belt that connects the Coast Range mountains and Sierras, above and around the head of Sacramento valley, where a few come down lower, in groups rather than groves, or very much more sparsely, where, also, they develop but few cones, comparatively, even in favorable fruitful seasons, and most of these, say two or more, become abortive, and it is well if even one of the number matures; besides, it should be noted the cones are smaller, yet always characteristic. Found more or less in all parts of the State, namely, on the Sierras from 3,000 to 8,000 ft. of both slopes, and a few in the highest points of the Coast ranges from Santa Lucia mountains to Humboldt county, and so on northward to the Columbia river.

Between the two forks of the Stanislaus river may be seen a tree 3,000 ft. high, and about 15 or 16 ft. in diameter.

Western Weymouth Mountain Pine.

(*Pinus Monticola.*)

* * * "Seemed an osprey,
Hovering above his prey—and yon tall pines,
Their tops half mantled in a snowy veil."

The far western mountain pine of the Pacific bears the strongest resemblance to the great sugar pine, of which it seems almost like a smaller variety of the same species (hence designated little sugar pine). The general contour and expression of the tree is scarce at all like the white pine (*P. strobus*) of the eastern Atlantic; true, it has the common cone characters of the thin scaled strobus section, and five-clustered needles as in Lambert's sugar pine also, but the port and form, as indicated, is as distinct as it well can be for one of the same subdivision of pines. Before the tree has attained to its true matured and distinctive type, it has the common closer form of many other species, but at length, when of age, and aloft from 75 to 100, or sometimes 175 ft. high, and from two to five feet in diameter, in full bearing, its long horizontal branches well poised and nicely plumed with little laterals and closed around with faintly softened sea-green leaves, two and one half to three inches short; and then there is the selfsame free spread of the great sugar pine, only peculiar to these two species; the five-leafed clusters of needles are set close together in short fugacious hoots, points sharp and edges keen, margins finely but remotely toothed, two sides channeled; the short but exceedingly slender foliage thrills very sensitively and delicately, the softer celestial echoes from off the blissful shore, to lull and soothe the sense to peace. Let other pines chaunt louder and grosser songs from their sylvan choirs where old Æolus dwells; these are of the higher angels who are wont to whisper their love notes low and still, as from the far away isles of the blest, soft as morning zephyrs gently roll the grain-clad dells. The form and size of the cones that cluster and tassel the tips of the branches are quite like those of the white pine (sometimes called the soft California white pine)—oftener a little longer; herein the resemblance is nearly perfect, being alike on short stems, cylindroid, four to eight inches long, one to two thick and stiffly curved; scales smooth, thin, loose, abrupt and mucro-pointed, but not prickly; seeds small, one fourth of an inch long or so, mottled or spattered with brown; wings from two to three times as long, widest near the middle, diagonally pointed, translucent-creamy, and more or less striped with brown; cotyledons, six to nine.

Contemplating these conifers, distant from their alpine eyrie, we behold the great sugar pine stretching his wide wing-branches against the sky, like a vast sylvan condor soaring aloft high up over all contiguous trees; so, also, is seen this lesser mountain pine as a sylvan osprey sailing serenely o'er the mountains—tree-hawk of the hills, circumspecting the groves!

The soft pine of the Pacific is found sparsely distributed over the Sierra Nevada mountains, at from four to eight or nine thousand feet altitude; timber similar to the white pins, but neither quite so white or soft, and the texture somewhat tougher.

* From "The Forest Trees of California," by A. Kellogg, M.D. Published by the State Mining Bureau, State Printing Office, Sacramento.

MIOCENE MAN.—Grant Allen, an English evolutionist, gives this imaginary picture of our supposed ancestor: "We may not unjustifiably picture him to ourselves as a tall and hairy creature, more or less erect, but with a slouching gait, black-faced and whiskered, with prominent prognathous muzzle, and large, pointed canine teeth, those of each jaw fitted into an interspace in the opposite row. These teeth, as Mr. Darwin suggests, were used in the combats of the males. His forehead was no doubt low and retreating, with bony bosses underlying the shaggy eyebrows, which gave him a fierce expression, something like that of the gorilla. But already, in all likelihood, he had learned to walk habitually erect, and had begun to develop a human pelvis, as well as to carry his head more straight on his shoulders. That some such animal must have existed seems to me an inevitable corollary from the general principles of evolution and a natural inference from the analogy of other living genera."

Mechanical Progress.

The Steam Engine Doomed.

Whatever else may survive in the future, Dr. Siemens is certain that the steam engine is doomed. Its fate is first to be confined to the driving of large dynamo machines, which will distribute force at present supplied by a myriad small and wasteful steam engines, and then to be superceded altogether by the gas engine. Gas and electricity may be mutually hostile, but they are to unite their forces in order to exterminate the steam engine. The unpardonable sin of the steam engine is waste. Even the best of them consume two pounds of coal per horse-power per hour; whereas, says Dr. Siemens, when the gas producer has taken the place of the dangerous steam boiler, it will not take one pound of coal to develop one horse power for one hour. But before gas banishes steam it will superceded coal as the agent for the development of steam. A pound of gas gives forth exactly twice the heat of a pound of coal, and even this may be improved upon. To burn raw coal is to squander our inheritance. Dr. Siemens gave some startling figures to prove that the by-products of the coal annually used in gas making are worth three million sterling more than the coal used in producing them, without allowing anything for the value of the gas. Besides the products already realized, 120,000 tons of sulphur are now wasted every year, which may yet be converted into a source of income. By abolishing the use of raw coal, Dr. Siemens maintains that science, as with some magician's wand, will "banish the black pall of smoke which hangs over our great cities, and restore to them pure air, bright sunshine and blue skies."

Nor shall we even have to suffer as compensation from the multiplication of enormous gasometers. The coal will be converted into gas at the bottom of the mine—a prospect not altogether to be contemplated without alarm by the workers in fiery seams—and the gas carried by pipes wherever it is wanted. Electricity will also be made largely serviceable for the distribution of power. Even after allowing 50 % for loss in transmission, the gain is still enormous. The electric light will chiefly be confined to lighting public places. The gas light will hold its own as "the poor man's friend," and gas heating will become universal. Thus, in the near future, Dr. Siemens unfolds before our eyes a world in which there will be no smoke and no steam, and where coal will only be visible in the immediate vicinity of the pit. Electricity will light our streets, gas will cook our dinner, and driving power will be laid on by wire wherever it is wanted. There will be no pollution of rivers, for every waste product will be utilized, and the sulphurous fumes which have converted whole counties into scenes of dark desolation will be employed in making the wilderness to blossom as the rose, and in restoring fertility to our exhausted soil. In short, science at last will begin to banish all the manifold abominations by which the "black age" of manufactures has defaced the beauty of our land. It is not before time.—*Pall Mall Gazette.*

Steam Engine Improvement.—This important improvement in steam engines appears, even to many experienced engineers, a sort of mechanical paradox. With but one crank, with two cylinders cast in one piece, and only one chest valve, the entire engine is as simple and few in parts as the simplest ordinary single cylinder engines. It has no dead centers, but will start forward from any possible position in which it may be placed. Further, it may be stopped, started and changed from a single to either a double or compound engine as may be desired, by the motion of a single lever, and the change to either form may be made while moving at any speed just as easily, it is asserted, as when it is still. The engineer can run it with one cylinder as a single engine, or with both cylinders, using live steam, as a double engine, or with one cylinder, using live steam, and the other running by expansion as a compound engine, either way as economically as any engine especially built for that particular way.—*Journal of Franklin Institute.*

Iron Working in India—The ancient inhabitants of India were remarkably advanced in the art of iron working. The famous iron pillar of the Kutab, near Delhi, indicates a skill in the manipulation of a large mass of wrought iron which could hardly be surpassed by modern foundries. The pillar is 23 ft. 8 inches in length, with a circumference of about 15 ft. at the base, tapering to about four feet just below its capital. Its total weight is over six tons. It is supposed by Mr. Ferguson to date from the year 400 of our era; and, if so, has stood exposed to wind and weather for nearly 15 centuries without signs of rust—an enduring monument to the skill of the old Indian iron workers.

Another.—Edison has recently secured a patent for a device for raising or lowering the electric light at will. The new invention is called an "adjustable resistance," and is operated after the manner of a German student lamp. The light can, by a single touch, be raised to its full power or lowered to a mere spark. The cost of the device is $2.50 for each light.

Smoke Consumption.

That much of the smoke nuisance complained of in cities might be avoided by care in "firing," is shown by the following: Some time ago the city of Chicago enacted an ordinance, requiring that locomotives within the city should consume their smoke. This resulted in experiments with various devices and fuels, but chiefly in the enforcement of more careful firing. Suits were brought against some companies for creating a smoke nuisance, but these were recently dismissed on the ground that the companies had complied with the ordinance. The Chicago *Tribune* has inquired into the methods used and reported as follows:

"We are using one smoke-burner," said Superintendent Lyford, of the Chicago & Eastern Illinois, "and it does away with the black smoke to a great extent, but sums still comes from the chimney. I watched the locomotive yesterday, and scarcely any smoke was to be seen. We are testing the burner, and if it works satisfactorily, we shall put it in all our engines. So far it is very satisfactory, but we are going to give it a thorough trial. We expect now that it will be a success."

"We are not using any smoke-burners," said an officer of the Burlington & Quincy, "nor have we changed our fuel. A compromise was effected with the authorities, and a man has been appointed to watch our engines and make complaints if too much smoke comes from them. The engineers and firemen have been instructed to be careful in firing. That is our remedy."

"There must be smoke to some extent," said Augustus Herrington, of the Northwestern, "but there is no necessity for so much as to be a nuisance. We have demonstrated that careful firing is the remedy. Smoke-burners themselves are a nuisance. Our engineers and firemen have been directed to fire carefully, and if they don't do it they will be discharged. Prof. Paton examined our road and became satisfied that we were not violating the ordinance."

"We are using coke," said Mr. W. B. Keep, Assistant Attorney of the Lake Shore & Michigan Southern. "It works all right, but is more expensive. Out on the road we burn soft coal. Every passenger locomotive has on 250 lbs. of coke when it leaves the depot, and that lasts until the city limits are reached. Coming in they take on coke enough at Forty-third street to get to the depot. The grates in the switch-engines which are running in and out all the time have been changed so that coke can be used, and that is the case, too, with the engines on the suburban trains. Now and then a freight engine runs in with soft coal, but the smoke nuisance has been done away with on our road."

A Fortune Saved.—Twenty years ago a large manufacturing concern in England, running several mills and using about 50 steam boilers, commenced to burn anthracite screenings under their generators in their different mills. When they first commenced this process this fuel was purchased very low, as it was then a waste and drug. With the improvements made in combustion, its use has now become more general, and the price has advanced, so that the difference now is only about two dollars a ton. Now, allowing that this difference is all that has been saved from the start, and estimate a daily consumption of one ton of fuel per boiler, doing a duty of 300 days a year, we find an economy of between $500,000 and $600,000 over what it would have been if lump coal had been used. This concern is now changing its boilers to use this fuel by utilizing the waste gases with hot air on top of the fire. As there is estimated to be millions of screenings wasted at the mines every year, it is astonishing none of the large cotton mills adopt this fuel. There are several mills in Lowell, Lawrence and Manchester that burn from 12,000 to 28,000 tons of lump anthracite coal every year, while actual experience has demonstrated that the screenings when properly fired will make as much steam per ton as the best grades.—*Boston Journal of Commerce.*

Large Engines Not Economical.—The division of driving power has become an important matter of consideration with manufacturers. Many are replacing one large engine by two or three smaller ones, so that needed repairs may not close all the departments at the same time. It has been suggested that electricity would, before long, furnish the artificial light for manufactories; so that if one engine is stopped another might drive the machines for providing the light. As an additional reason in favor of this division of power, when occasionally only certain departments require over-time work, a small engine may supply the need and save the expense of running the shafting for the whole of the machinery.

Dimensions of Steam Boilers.—Different makers differ in their rules for dimensions of boilers. The following estimates, however, are safe: For each nominal horse-power a boiler should have one cubic foot per hour, one square yard of heating surface, one square foot of fire-grate surface, one cubic capacity, 28 inches flue area, 18 inches over bridge.

Care of Boilers.—In tubular boilers the hand holes should be often opened and all the collections removed from over the fire. Also, when boilers are fed in front, and blown off through the same pipe, the collection of mud or sediment in the rear end should be often removed.

Scientific Progress.

A Snake Turned to Wood.

The scientific world is indebted to Lenpor Lopez Netto, the Brazilian Minister to the United States, for introducing to their attention the evidence of a phenomena, which, although it may have been regarded as possible, has never before been observed—that of an animal turned into wood. The specimen is that of a snake called the jararaca, one of the most venomous reptiles of the province of Mattn Grosso, Brazil, which, having crept into a crack in the bark of a tree, has died there, and afterward become lignified. The head, neck and other parts of the animal are clearly delineated, and the most delicate details of the organization are plainly visible in many regions—as in the nostrils and the eye cavities, and in the disposition of the scales. M. Louis Olivier, of the Botanical Society of France, who has made an anatomical examination of the figure, reports that he has found it to be composed of cells and fibers like those of the secondary wood which surrounds it. "The formation," he says, "cannot be explained by saying that it has resulted from the disposition of the elements in a hollow, which, having been traversed by the animal, has preserved its form; for not only the contour of the serpent, but the whole relief of its form, is recognizable in the wood. The entire body of the animal has been thus lignified, except the center, where the constituent elements of the animal still exist."

Following the line of the projection of the head, and about an inch distant, was found a cylindrical figure, also in relief, which seems to represent the larva of an insect. The deduction is, therefore, drawn that the reptile, pursuing the insect into a crack in the tree, had insinuated itself between the wood and the bark, or into the zone of the cambium, out of which the wood and inner bark are formed. Having died there, it went through the process of decay, in the course of which each animal particle, as it was dissolved, was replaced by a particle of woody tissue deposited by the cambium. The specimen was exhibited to the Botanical Society of France on the 9th of April last, and is the first reliable instance on record of a gradual substitution of ligneous fibers and cells—the generative tissues of plants—for the constituent elements of animal life and substance. As rapidly as the flesh decayed, its place had been occupied by the cells produced in the natural growth of the wood—just as minerals are so often found to occupy the cells of vegetable or animal matter, as it passes into decay under favorable conditions for such substitution. A full account of this interesting phenomena is given in the *Popular Science Monthly* for November, accompanied with a well-executed pictorial representation of the fossil snake, as shown in relief upon a section of the tree upon which it was found.

The Origin of the Diamond.

A. B. Griffiths, F. C. S., etc., in the *Chemical News* says: "We can theoretically account for the formation of crystalized carbon in nature, although scientific men generally hold the opinion that the origin of the diamond is entirely unknown. We know that the diamond has been found in a fine-grained sandstone in Brazil, and is principally found in an alluvial matrix of sand and quartz pebbles. Knowing these facts, and that there are only three methods by which crystals are formed, namely, by fusion, by solution and by sublimation; and as the diamond has been found in sedimentary rocks, and in an alluvial matrix of sandstone and pebbles, and knowing that sandstone and pebbles are produced by the action of water, hence their name of aqueous rocks; and as aqueous or sedimentary strata are often fossiliferous we may draw an inference that the carbonaceous matter of the fossils (plant and animal remains) has been dissolved by highly heated water, aided by great pressure existing in the crust of the earth.

"It is a well-known fact that highly heated water, aided by pressure can dissolve silica, as in the Geysere of Iceland, etc., where it is deposited around the mouth of the vent, forming 'the sinter,' and also we have the experimental researches of De Senarmot (*Ann. de Chimie* III, xxxii, 129), and others on the artificial production of crystalized minerals, as quartz, mispickel, corundum, heavy spar, etc., by the prolonged action of water at high temperatures and pressures, and I think we can see no reason why highly heated water or water gas should not have the power of dissolving the carbonaceous matter of fossiliferous plants and animals and then on cooling depositing the carbon in the crystallized condition, forming the gem known as the diamond. As to whether the diamond was formed by sublimation we can draw no inferences from facts or from nature, so must put this method of forming crystals on one side as not being able to solve the problem; and further, the diamond cannot be formed by fusion, because we know that crystalized carbon in the form of graphite is formed by fusion (as 'kish' in the manufacture of pig-iron).

"Therefore, it appears from these views on the subject that the diamond has been formed in nature by the solvent action of highly heated water or water gas, aided by enormous pressure on the carbonaceous matter of fossils contained in sedimentary rocks followed by slow cooling."

Porosity of Rocks.

At the recent meeting of the British Association, Mr. C. E. De Rance read the report of a committee appointed for the purpose of investigating the circulation of underground waters in the permeable formations of England, and the quality and quantity of water supplied to various towns and districts from those formations, to which was added an appendix on the density and porosity of rocks, in relation to the water supply. A knowledge of the porosity of rocks was stated to be important as regards the water supply, the suitability of stone for building purposes, and in accounting for some of the lithological changes often observed in the strata of the earth. Though the matter had not escaped investigation, the vast volume of water stored in rocks had not been fully realized. The density of the old red sandstone was 2.61, the volume of water absorbed by a cubic foot being over .707 gallons, and by a square mile 3 ft. thick 59,000,000 gallons. Conglomerate beds of the same formation are still more absorbent, being capable of taking in .85 gallons per cubic foot, or 67,000,000 gallons per square mile, 3 ft. thick. The millstone grits which lay at the base of the coal measures vary much in different localities, that found in the forest of Dean being most porus and absorbing 66,000,000 to the square mile, 3 ft. thick. Some of the coal measure grits also stored large volumes of water. The Peunant rock, 900 ft. thick, in the Bristol coal field, was capable of absorbing 12,000 gallons in a square mile 3 ft. thick, and specimens of magnesian limestone taken from the neighborhood of Bristol gave 86,000,000 gallons, but the carboniferous limestone was quite the reverse, absorbing only 3,500,000 gallons. Oolites were stated to hold vast stores of water, and the rock was used extensively for building purposes. From an analysis of rocks it is clear that nothing in their chemical composition could purify the water, and in order to get rid of organic contamination, there must be oxidation, and the oxidizing agent was considered to exist in the air, absorbed by the water and the air contained in the interstices of the rock.

The Alcohol of Fermented and Distilled Liquors.—It has generally been assumed that the alcohol of fermented and distilled liquids is identical, but it is by no means certain that such is the case. We know, says the *Brewers' Guardian*, that alcohol is produced by fermentation, and can be concentrated, and even isolated, by distillation, but it is possible that the action of heat necessary for distillation modifies and perhaps changes the chemical constitution of this substance. Although there is no direct evidence of the existence of these two kinds of alcohol, it is not altogether unreasonable to suppose that the action of heat causes a partial dehydration, and that in this way the alcohol of distilled spirits differs somewhat from the alcohol of fermented liquids. This hypothesis is supported by the well-known fact that distilled spirits have a different and more injurious effect on the human system than the alcoholic liquids produced by fermentation. Medical men often prescribe beer and wine, but prohibit the use of brandy, whisky, gin and all spirits which have undergone the process of distillation. It is within the personal experience of many that a wine which has been fortified by the addition of distilled spirits is far more potent and, we may even say, unwholesome, than a wine of equal alcoholic strength, but produced by fermentation only; in like manner we believe that a larger quantity of alcohol may be safely consumed in the form of beer than in that of spirits. The question deserves further investigation, not only in the interests of the brewing trade, but in the interests of temperance and health.

The Efficiency of Washed Coal—Though it is generally conceded now that wet bituminous coal will not make as large a quantity of steam in a boiler as dry coal, there are few figures to substantiate this. There have been firemen, and there are some now, perhaps, who insisted that their coal yielded better results after it had been liberally moistened than when dry, but of late that idea has lost ground, and, as a general rule, has been condemned. A series of tests has recently been made at Bochum, Germany, which offers facts in place of theoretical considerations. A quantity of washed slack, holding 18% of water and 9.9% of ash, evaporated 5.7 pounds of water per pound of fuel, while the same coal, with only 3% of water, made from 8 to 8.5 pounds of steam. Making due allowance for moisture by reducing to a standard of like quantities of coal free from moisture, there is found to be a direct loss by using wet coal of 14%.

Examination of Glass.—The author applies the known blowpipe reactions. Lead in glass or enamel is detected by beating for a minute or two a bead of the sample fused to the end of a small glass rod. Glass free from lead shows no change. Specimens containing much lead blacken, and the bead becomes opaque. Green cupriferous glass, if beated in the reduction flame, is colored in parts an intense purple red. The simultaneous presence of lead masks this reaction. If a fragment which is to be tested for copper or gold is beated in a glass tube, and if both are drawn out a little while soft, the color due to gold remains unchanged, while red copper-glass becomes perfectly colorless.—*Max. Muller.*

Mining Share Market.

As onr stock tables show, there has been a pretty good market of late, it having "braced up" to some extent. The Comstocks were mainly dealt in.

It will require some four or five weeks yet to make the connection on the 2900 level between the northwest drift of the Mexican and the south drift in the Union Consolidated. As soon as this connection is made and the necessary drain cut, an npraise will be made to the bottom of the winze down from the 2700 level, first tapping the bottom of the winze with the diamond drill to draw off the water. Here will then begin other interesting prospecting operations, and at the same time explorations will be commenced at the 3100 level in Ophir and Mexican.

Meantime the Chollar drift is going south toward the Potosi ground, and something of interest is liable to occur there or at some other point in the middle mines at almost any time.

At Gold Hill the situation is becoming somewhat interesting, as a contest is about to be commenced over the ore discoveries made in the Kentuck ground by C. C. Stevenson, the leaser of the mine. The *Enterprise* thinks that the indications are that a mineral belt parallel to but onteide of that worked in early days has been cut into, and the Crown Point and other companies adjoining the Kentuck are exploring for this new seotion.

News in Brief.

THE artesian well at Weed Island is down nearly 500 ft., and no flowing water found.

The Socialists continue to hold large and enthusiastic meetings in all parts of France. Gambetta's name when mentioned is received with hooting.

A DISASTROUS fire has occurred at Margate, England. The Assembly rooms, vicarage and one whole side of Cecil's Square are burned, Lose, £300,000.

THE Philadelphia Musical Festival Association has been organized, with a guaranteed fund of $30,000, for the purpose of getting up a festival in April.

A SUIT at law is pending in Ohio against a telephone company which removed a telephone from plaintiff's premises "because of the use of profane language."

THE Flint cotton print mill at Fall River was burned Saturday. The total loss, including the mill, machinery and goode in process of manufacture will be about $750,000.

SETH GREEN will start for Florida about the middle of Novemher, to study the habits of migratory fish, under inetructions from the State Commissioners of Fisheries of New York.

IN the season of 1881–82 more than 3,000,000 trees were planted in Great Britain, out of which number Scotland claims about 2 000,000, England, 600,000, Ireland, 300,000, and Wales 40,000.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Benson Mining and Smelting Co.—October 30. Capital stock, $3,000,000. Directors, Alfred Eoff, Solomon D. Barstow, Edward B. Young, San Francisco; Henry Wadsworth, Joseph S. Robeson, Oakland.

Buckskin Con. M. Co.—October 30. Capital stock, $10,000,000. Location, Sawtooth mining district, Alturas county, Idaho Territory. Directors, George S. Evans, E. J. Moore, Wm. H. Sharpe, Patrick J. White, Peter B. Quinlan.

Recent Contributions to the California State Mining Bureau.

Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANKS, State Mineralogist.]

[CATALOGUE.]

4227. Fragment from a Bowlder of Basaltic Lava—Concave on one side, convex on the other, showing how angular fragments of rock weather into rounded bowlders, without water-washing. Plains between Oroville and Pence, Butte Co., Cal.

4228. Basaltic Lava, Showing a Scale—Which is due to oxidation of iron to limonite. Near Doon's Mill, Butte Co., Cal.

4229. Persberglite (Cordierite) (Dichroite)—Persberg, Sweden.

4230. Silver Ore, Jones Mine—Four miles from Angels, Calaveras Co., Cal. W. H. Porter.

4231. Chalcopyrite, Illapel Copper Mine—Coplapo, Chile. F. Casanueva.

4232 Pyrite and Chalcopyrite—Coquimbo, Chile. F. Casanueva.

4233. Iron Ore, Pacific Coal and Iron Mine—Skagit River, Washington Ter. Henry Abbot.

4234. Free Silver, in Gangue of Barite—Waterman & Porter mine, Grapevine District, San Bernardino Co., Cal. J. S. Waterman.

4235. Coal—Monterey Co., Cal., Township 22 South, Range 13 East, Mt. Diablo Meridian.

4236. Mica Schist—Berkeley hills, Alameda Co., Cal. Robert Walkinshaw.

4237. Brozzite—Berkeley hills, Alameda Co., Cal. Robert Walkinshaw.

4238. Magnetic Sands—Mouth of Russian river, Sonoma Co., Cal. Robert Walkinshaw.

4239. Schist with Garnets—Mouth of Russian River, Sonoma Co., Cal. Robert Walkinshaw.

4240. Chalcopyrite, Sulphides of Copper and Iron—Karta bay, Alaska. Caleb T. Fay.

4241. Fossils in Sandstone Undetermined. Found with Ilgnite. Wrangel Land, Corwin Expedition. J. B. Haggin

4242. Rock Specimen, marked "Iron Ore"—Chimney Rock mine, Township 4 South, Range 10 West, Mt. Diablo meridian. This is certainly not an iron ore, although it seems to contain specular iron in small quantities.

4243. Lithographic Stone?—Santa Maria, near Mulege, Lower California, Mexico.

4244. Deposit from Paso Diablo Springs, Inyo Co., Cal. S. D. Woodbull.

4245. Jacobsite—Jacobsberg, Sweden.

4246. Specular Iron—Sierra Madre, between San Ignacio and San Boxas, Lower California, Mexico. J. G. Moraga.

4247. Foliated Talc, with Chalcopyrite—San Diego Co., Cal. M. J. Amick.

4248. Indian Mortar—Dogtown, Butte Co., Cal.

4249. Alum Slates—Near Auburn, Placer Co., Cal. G. H. Hawes.

4250. Alum—Crystallized from No. 4249. Near Auburn, Placer Co., Cal. G. H. Hawes.

4251. Alum Schist—Oregon, near the line of Baker Co. and Nevada. J. C. Weir.

4252. Alum—From No. 4251, which see.

4253. Magnetite—Suoquatnie Pass, Cascade mountains, Kings Co., Washington Ter. John Leary.

4254. Iron Ore—Magnetite—Clarksville, El Dorado Co., Cal. T. B Everett.

4255. Fragment of Diorite?—Changing to a pebble without the agency of water. See No. 4227. Owl's Head Mining District, Pinal Co., Arizona. Wm. Clarke.

4256. Obsidian Arrow Heads—Sonoma Co., Cal. J. H. Butler.

4257. Copper Ore—Genessee valley, Plumas Co., Cal. B. D. Russell.

4258. Sandstone?—(Stained Red). Santa Margarita ranch, San Diego Co., Cal., near San Luis Rey. Chalmers Scott.

4259. Glaucophane Rock—Wall rock of the Collier mine, six miles northeast from Murphy's, Calaveras Co., Cal. Richard Cohen.

4260. Chalcedony—Boxas, Lower California, Mexico. J. G. Moraga.

4261. Thinolite, Branching from a Shell—Union, Humboldt Co., Nevada. J. K. Colerick.

4262. Lepidolite, Pink and White with Azurite—Vein matter of the Half Dollar mine, Inyo Co., Cal. Shaft, 75 ft. deep. Morris Burke.

4263. Sepidolite—Half Dollar mine, Inyo Co., Cal Morris Burke.

4264. Erubescite—Arctic Lode, Du Cahezas district, Cochise Co., Arizona. Said to have yielded iridium at the United States Mint at New Orleans, but this is probably a mistake. J. D. Emerson.

4265. Lava, with Zeolite—Eureka, Humboldt Co., Cal. Geo. C. Purvis.

4266. Hornblende Rock—Gold Run, Placer Co., Cal. Levi Dorman.

THE governments of England, Germany, France, Austria, Belginm and America have declared their intention to support the proposed International Agricultural Exhibition to be held at Hamburg next spring.

THE Central Pacific railroad company's new steam collier is nearly ready for sea, and will sail direct for San Francisco in the course of 10 days. Her sister ship, the *San Pedro*, will follow in the course of three weeks.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

JACKSON.—Amador *Ledger*, Oct. 28: Sinking operations are being pushed ahead, with the intention of putting down the shaft to the depth of 300 feet and opening up a level at that depth. If the ledge at this depth is found to hold its own in size and quality, it will afford good grounds for believing the ore body is permanent. The Moore mill is kept running steadily on rock from this mine. A clean-up will not be made for two or three weeks yet, and this alone will demonstrate the paying quality of the rock. The mill is thoroughly equipped with the best appliances for saving both gold and sulphurets, and is in charge of Messrs. Howard & Hopkins, both experienced millmen. It costs 75 cents per ton to haul the rock from the mine to the mill, and to leave a fair margin for profit it will have to surrender about $10 per ton.

MISCELLANEOUS.—In prospecting on the Moore mine lately two quartz ledges have been cut. One is 14 ft in width, and believed to be identical with the ledge in the main shaft. Another distinct ledge, said to be 7 ft wide, has also been struck. Careful prospecting from rock taken from each of these ledges failed to detect a trace of gold. In the face of this result it is not probable that much more will be done in the way of developing this claim.

THE London mining company, J. R. Johns, superintendent, have concluded to withdraw from Amador county. This is the worst news we have had to chronicle for a long time. This company has been the most unsuccessful of all capitalists that have invested money in mining ventures in this county. Formerly they operated the Original Amador, at Amador City, and abandoned it about 2 years ago, after expending something like $2,000,000. Since then they have done some thorough exploration on the Maryland property, near Drytown. Operations here have likewise proved barren of result, and work was suspended on the first of this month. The company will sell the machinery and real estate, and wind up usiness here.

BUTTE.

MAGALIA GOLD.—Oroville *Mercury*, Oct. 28: The Magalia gold mine, at Magalia, is probably the most valuable piece of property of the kind in this county. The tunnel through which the mine is worked is over 2,200 feet in length. The gold is found in an old channel of what was once a small stream. In some places it was once a narrow stream of 2 ft in width; in others it widened out to from 10 to 20 ft. The gold is coarse lumps, weighing as high as $400 in value. Just now the men are working in one of the wide places, and the gold is found in quantities that border on the marvelous. Five men work on each shift, and there are 2 shifts in 24 hours.

OREGON GULCH MINES.—Cor. Butte *Register:* I would call your attention to what is being done in quartz in this gulch and vicinity. The first I meet with is the new discovery made by D. W. Reece, who has a fine two-compartment incline down 50 ft on the ore vein, which averages over 2 ft in width, and will mill from $10 to $60 per ton. Mr. Reese has just struck into ore that prospects 25 cents to the pan. On this mine there is a small five-stamp mill run by steam power, and a deisy of a mill it is too. It does splendid work, and is just the thing to prospect a mine with.....In passing down the gulch we met Mr. Lew Brown, who is developing his mine with all energy and enterprise.....C. W. Keney seems to be pushing forward work on the old Banner.....Adjoining the Banner is the Minerva, which is trying to do something, but needs a good man at its head, in order to turn out the bullion that it is fully able to do with proper management.....For the short time that I have been in this district I can safely say that there is untold wealth in the quartz mines in this district, and it only needs good, enterprising men, with some means, to make them a large source of revenue to the town of Oroville, and the attention of quartz men should be called to this district, for it is one of the best in the whole State for investment.

A PAYING MINE.—Butte *Record*, Oct. 28: The Pershacker claim at Magalia, is still producing large quantities of rich gold. As a result of a three days' run $5,000 worth of gold dust was cleaned up last week and taken to Oroville on Tuesday for shipment. The largest piece of gold weighed nearly $180. The Oroville *Daily News* says: "The breast of the drift is now nearly 50 ft in width, and the gravel is growing richer as work progresses. But 5 men constitute a shift—3 men working at the face of the drift, one wheeling the gravel, and the fifth is employed in hoisting it to the surface. They are not bothered by water any more, having pumps of sufficient capacity to control all the water that comes into the claim. The tunnel is now in about 2,000 feet. But 15 men, altogether, are employed about the mine."

INYO.

THE MONTEZUMA.—Inyo *Independent*, Oct. 28: Mr. S. D. Woodhull writes some brief notes from the Montezuma works, as follows: "We are getting along finely with the furnace. Stetson & Hedge have got the boiler and engine nearly ready to get up steam. I have got the furnace foundation up, and nearly ready for the jacket. Ten days more will come pretty near completing the thing. We have a working force of 14 men, and all works smoothly so far. Assay office complete."

MARIPOSA.

DILTZ MINE.—Mariposa *Gazette*, Oct. 28: We learn that Mr. Diltz has had a new water ditch surveyed from the Falls at Sherlocks around to the mill site at the north end of his mine. We understand, further, that he is making arrangements to have his nephews, now resident in Indiana, come out here and help him in working his mine, in case the proposed sale of it should fall through.

MONO.

STANDARD CON.—*Free Press*, Oct. 26: There was extracted during the week 1,436 tons of ore. Crude bullion received, 4,795 ozs, and shipped to the company $20,031.69. The west crosscut, 1000 level, is in 1,034 ft; progress during the week, 16 ft. There is no change to note in the character of the rock cut through. The east crosscut from the south drift has been driven since last report 20 ft; total depth, 50 ft. The face is in very hard ground. The Cook upraise has reached a hight of 250 ft; progress, 15 ft, showing four ft of vein.

PLACER.

PLACER'S QUARRIES.—Placer *Herald*, Oct 28: The Taylor brothers are working a number of men in their quarry at Rocklin, and a comparatively small force is employed at Mr. Griffith's quarry at the same place. At Penryn Mr. Griffith is doing considerable work; at Fino, also, some work is being done. The other quarries are doing very little. It is expected that the Placer county quarries will get the contract for the stone for the Government dry dock, which of right, considering the superiority of their stone, they ought to have. If successful in this expectation times in the quarries and with the quarrymen will be very lively for some time to come.

THE BOB LEWIS CLAIM.—The Bob Lewis drift claim at Damascus, owned by Lewis & Griffith, as at present opened up and developed, promises to take rank among the very best drift mines of California. The owners have delved and delved in this mine, have run many hundred feet of hard bed-rock tunnel, but at last have come upon one of the best defined channels we have ever seen underground. It is of great extent, and the gravel is of a high grade. Whether the worthy owners work the mine or sell it they have their fortune. They are quiet, industrious men, are making no great splurge, but they have a mine of true merit.

MINE IMPROVEMENTS.—Mr. Peardon, one of the proprietors of the Morning Star, or what is better known as the

old Shipley mine, from which 371 ounces of gold was brought last week to the banking house of Andrews & Hollenbeck, informed us that they are about to erect such hoisting works that will enable them more rapidly to develop their mine by increasing their working capacity. This mine has paid very liberal dividends from the start, and their present prospects warrant them in making a liberal outlay for machinery. They intend to put up an engine of sufficient capacity to enable them to greatly increase their workings. Messrs. Peardon & Hawkins, the proprietors, are two energetic and enterprising young men, and they believe that they have in their mine an almost unlimited source of wealth.

A Good Prospect.—We learn from Albert F. Mundt, a young miner of vim, enterprise and industry, that he is opening up a new ledge on Bellevue hill, north of Ophir, and that it prospects very encouragingly. From a crushing of about 8 tons, recently put through the mill, he realized about $29 per ton, which was much better than he expected. The outlook for Ophir district is better now than it has been for a long time, and we are pleased to note the fact. There are many first-class men and miners, both young and old, in that district, who have stuck with it through thick and thin, through good and bad repute, and they deserve success.

The Weske Mine.—During our rounds recently we visited the famous Weske drift mine at Turkey Hill, near Michigan Bluff, and were pleasantly surprised to note the wonderful improvements being made under the supervision of the Muir brothers. They are working a great many men, and are struggling to work the mine on a scale that will be simply gigantic. Their main tunnel has been enlarged and straightened, a large lot of new and improved iron cars have been received, a large new dump is being built, a new lodging house of extensive proportions is near finished, and they are preparing to put on a locomotive to haul the cars in and out of the mine. What is particularly gratifying, the mine is paying for all these costly and extensive improvements as they go along, and when they are once finished and all is concentrated on the taking out and washing of gravel, the profits, as can readily be understood, must necessarily be large. All these great works are conducted without any jars or gratings, a fact that speaks volumes for the management.

SAN BERNARDINO.

Calico Items.—*Print*, Oct. 21: The Four Aces are working as heretofore. The vein is looking fine as the shaft goes down. Work is being prosecuted at the Cuba No. 1 vigorously. They have made a new find of ore, and the mine is looking splendid. On the Bismarck work is going ahead. They are packing ore from the mine down to town on burros. It is to be shipped to the Oro Grande mill. At the Snow Bird mine they are assorting and re sacking ore for shipment to Sherman's mill, under the management of Mr. Sinclair, assayer. Developments at the mine are very satisfactory to the owners. The Great Eastern mine, located east of the Occidental group, has two men at work running a crosscut, the ledge showing ore, and developing better daily. Good ore has been struck on the Lookout mine, owned by the Silver King company. This ledge is one of the best prospects in West Calico. Capt. Covington has just finished a good trail to the Bedford Forest mine, connecting with the wagon road leading out to the west end of the mountain to Fish Ponds. The Bedford Forest company are now shipping ore to the arrastra at Fish Ponds. The Silver Odessa mine has three men at work running an open face across the ledge. They intend to start tunnelling as soon as face enough is had. The vein in the open cut appears to be about 20 ft in width, and looks better than ever before. Wiseman & Morris, owners of the Dragoon mine in Deep canyon, have commenced sinking a shaft. They are now down about 10 ft, the vein appearing 8 ft wide, carrying chloride ore which assays as high as $400 to the ton. Ore will be shipped to the Oro Grande mill until rates can be obtained from the railroad company, when they may ship it to San Francisco and sell in open market.

SIERRA.

Quit Work for the Season.—*Foothill Tidings*, Oct. 28: The Grass Valleyans, who were at the Jim Crow mine, in Jim Crow canyon, Sierra county, have quit work for the winter and returned home. A man was left in charge of the property, and he has a full supply of everything he may need while he is snowed in. The work done so far was in the way of prospecting, and the result has been very satisfactory to the owners of the mine. Next spring work will be resumed there, and will be vigorously prosecuted.

NEVADA.

WASHOE DISTRICT.

California.—*Enterprise*, Oct. 30: On the 2700 level the joint Con. Virginia southeast drift has been advanced 22 ft. Are extracting ore from the croppings.

Sierra Nevada.—Connection has been made between the north and south drifts on the 2700 level. Are now cutting out a drain and timbering up.

Con. Virginia.—The joint California southeast drift, 2700 level, has been advanced 22 ft. The southeast drift, on the 2500 level, has been advanced 17 ft.

Ophir.—The main south drift, 2900 level, has been extended 15 ft, and are now cutting a drain and timbering up. During the week 148 tons of ore have been extracted from the croppings.

Union Con.—Upraise No. 3 from the 2650 level has connected with the 2600. The west drift on the 2600 level has been extended 21 ft.

Chollar.—On Saturday last a drift south was started from the west drift, 2600 level, and is now in 80 ft, the face in vein porphyry and quite dry. Some seams of quartz of better character than anything heretofore found on this level have been cut through. The quartz carries a little precious metal, assays averaging about $5.

Yellow Jacket.—The water has risen 12 inches during the past week, and to-day stands 1,154 ft above the 3000 station level. On the Sazebrush level we have extended the north drift 40 ft, the face of same being 440 ft from the switch. The 300, 400 and 500 levels continue to yield the usual quantity of ore of about 35 tons daily. Number of tons shipped during the week, 256. A partial shipment of bullion was received from the Brunswick mill on the 23d inst., amounting to $7,038.70.

COLUMBUS DISTRICT.

Northern Belle.—Candelaria *True Fissure*, Oct. 28: The same formation is showing in the face of the main drift on the fifth shaft level. A distance of 12 ft has been made in ground that yields well. Crosscut No 1 on the same level has been extended 11 ft, its entire length being 24 ft. The air connections on the second shaft level are fully completed, giving ample facilities for the extraction of ore. The upraise from the first shaft level is showing a promising outlook, the ore being of a very good grade, and 4 ft in width. The other shaft levels present no change of note. There is no material change in the levels above the adit. The stopes on the 9th and 10th levels are looking very well and yielding as usual. Drifting is still progressing to the south from winze No. 2, below the 10th level. This drift has been extended 40 ft, the entire distance in ore of good grade. The crosscut on the 11th level has connected with winze No. 1 from the 10th level, and everything is now ready to begin a complete prospecting of this 11th. Everything is running smoothly in and about the mine, and the daily output of ore is about 65 tons. Mill No. 2 is running steadily and doing good work. The bullion shipments amounted to $22,197.40 for the week ending October 25th, and aggregate $77,102.33 on October account to the same date.

LEWIS DISTRICT.

Betty O'Neal Mine.—Lewis *Herald*, Oct. 26: The south drift in the 260 level has been advanced 17 ft during the week, and the face is now in good ore. The crosscut west has been advanced 16 ft during the week on the same level. About 30 tons of first-class ore is on the dump. A station is to be cut on this level, and a tank put in preparatory to sinking another 100 ft. The Tributers on the Chloride mine have had their ore worked in the Highland Chief mill. We did not learn the result.

Morning Star Mine.—The Mayo incline has been extended during the week 8 ft, making a total depth of 299 ft, or 71 ft below the third or 228 level. The north drift third level has been advanced during the week 8 ft—total distance from incline, 94 ft. The face of the drift is in 54 ft of fair grade ore, the quartz being very hard, which accounts for the slow progress that is being made. The ore in this drift will average nearly 4 ft the entire distance. The south drift third level has been started, and is in 3 ft of fair ore. The new iron buckets lately purchased in San Francisco work splendidly, and at least 30 tons of rock can now be hoisted daily. Everything in and about the mine is working well.

MOUNT ROSE DISTRICT.

Spring City.—*Silver State*, Oct. 27: Ten miles north from Paradise is a village in the mines, Mount Rose district. There seems to be very little doing, owing to drawbacks such as many good camps get, from which it is often hard to recover; but from the surface appearance, there is bound to be good mines there, and a bright future is in store for this place. The mines furnish good ore, and one mill is running successfully.

PINTO DISTRICT.

Ore. Eureka *Sentinel*, Oct. 28: The first shipment of ore from the Silver Nugget, one of the Silver Nugget series, was made Wednesday. The ore is high-grade lead ore. The boys feel good over it, and are laying in a big supply of provisions for the winter.

SANTA FE DISTRICT.

A Good Prospect.—*True Fissure*, Oct. 28: Some time ago a discovery was made in Santa Fe district which bids fair to develop into a good paying property. The claim bears copper in great richness, assaying as high as 65 . I. B. Giles is the principal owner, and is very proud of his Calamity, as well he may be. It is situated about 3 miles east of the town of Luning, and can be seen very plainly from the back door of his place of business. He has some specimens that are exceedingly pretty, and he is proud of his find.

SILVERADO DISTRICT.

Shipment.—Eureka *Sentinel*, Oct. 28: The Berryman brothers, working on the Diagonal mine, will make a shipment of fine ore about the first of the month. They have laid in a big supply of winter provisions, and they have their workings in such shape that they think they will be able to ship ore continuously after they get started.

TYBO DISTRICT.

Full of Ore.—Cor. Belmont *Courier*, Oct. 21: Owing to the non-arrival of some engine castings, the Tybo mill did not start up on the 10th inst., as was intended, but will be delayed until the 15th. Every space about the mine is chuck full of ore, and a long run is anticipated. The 2-G mine never looked better. Mr. N. S. Trowbridge is making a splendid success where others failed in the management of the Tybo Con. mining company's property. He paid off his men 3 days ahead of time.

ARIZONA.

Steeple Rock, Dos Cabezas and Tevis Districts.—Tombstone *Republican*, Oct. 26: Dr. C. W. Barrow, an old and experienced mining man, whose opinion regarding mining claims has frequently been backed by plenty of capital, returned to Tombstone a few days ago. The Doctor said that he had just returned from the Steeple Rock district, via Tevis and Dos Cabezas. Dr. Barrow is not wildly enthusiastic over Steeple Rock, though admitting that there are some very promising claims in the district. The general characteristics of the district are small and extremely rich veins. The Carlyle is a very fine property, showing a vein of good mineral from 4 to 18 ft wide. There are four locations on the Carlyle vein, being extensions of the parent mine. These claims are looking very well, but are as yet but partially developed. Of those the Rain-in-the-Face seems to be the most promising. This claim yields up slabs of horn silver as thick as a man's hand, and the ore all through the ledge will give an average assay of $100 to the ton. Copper predominates throughout the district, but the ore also carries a fair percentage of silver. Dr. Barrow thinks that there is a bright future before Steeple Rock, and that with the introduction of a little capital, and consequent development, the district will take its place among the leading mineral depositories of the country. On his way to Tombstone Dr. Barrow stopped at Tevis and Dos Cabezas, and was favorably impressed with the progress and prospects of those camps. The Mineral Park is a splendid property, and is at present in course of development as rapidly as possible. The Cincinnati M. and M. Co., of Dos Cabezas, have started up with a full force. The First Chance mine is showing up well, and turning out the best quality of ore yet extracted in the district. It is the intention to remove the mill to the mine if the developments so warrant. The Commonwealth is also working a full force, and some fine ore is being extracted. According to Dr. Barrow, Dos Cabezas is on the eve of a general boom. Her mines never looked better, and those interested in them had never more faith in their perpetuity.

Tombstone.—*Republican*, 28: Things are running along about as usual. The great producing mines are yielding up about the same quantity of wealth as in the months past, while development progresses with avidity on the smaller claims in the western portion of the district. There is no doubt but that there is more real work performed in this district at the present time than at any period of its history. The camp has left that state of wild, reckless boyhood which characterized its early history and settled down to a life of calm, sensible, deliberate manhood. The Ingersoll, which has not less than 1000 tons of ore on the dump, will commence reducing at the Girard mill in a few days, and thus introduce another hullion producer to the camp. Some of the richest of the Ingersoll ore has been sacked, and will be sent to the Benson smelter to be reduced, by way of an experiment, to determine whether milling or smelting is best adapted to the quality of the ore. The Bandolph, Blue Jacket and Little Devil are still on the up grade, and there is hardly a doubt remaining but that they will take a front place as bullion producers at no distant day. Taking all in all, the prospects of the camp never looked brighter, and we may fairly look for a vigorous and extended boom at no distant day.

Mohave County.—Prescott *Courier*, Oct. 28: Mr. Ike Goodman, of Signal, was in Prescott Saturday last. Signal was a few years ago the best mining camp in northern Arizona, and will, Mr. Goodwin thinks, soon again enjoy that proud distinction, as the McCrackin mill and mine will soon again be in operation. A great many miners and road makers are at work in Cedar Valley district, north of Signal, where there is a mill and promising mines. A short time ago a ledge of rock rich in gold, silver and copper was discovered on the west side of Wallapai mountain. The discoverer was offered a large price for the property, but preferred to hold on to it. As the A. & P. railroad will run pretty close to Signal and supporting country, its citizens have hope that an active era will shortly dawn upon them. Besides mines of gold and silver, there are in this section a great many good-looking copper properties. The Planet mine alone has yielded about half a million dollars worth of copper.

Santa Domingo District.—Cor. *Arizona Citizen*, Oct. 29: The Oriole company is pushing work night and day on the Excelsior and Hilo Verde. A large force of men are employed, and the ore on the dumps accumulating rapidly. The main shaft of the Excelsior carries 4 strata from 6 to 14 inches in width, containing black metal, chloride, horn silver and argentiferous galena. These strata are gradually converging to a point of concentration, and at their confluence a large deposit of rich ore is anticipated. The west drift in this mine is also in ore of an exceedingly rich character. None of the ore is being hoisted to the surface, and the foreman is very reticent regarding information concerning the richness of this new bonanza.

Hilo Verde.—The east drift of the Hilo Verde encountered during the week a deposit of very rich ore, which, though not extensive, amply recompenses the owners for the cost of extraction. A perpendicular shaft to connect with the lower level will be sunk on this mine at an early date.

The Wirt and Picacho Mines.—Work was commenced a short time since on the Wirt and Picacho mines, and the showing made to date is flattering in the extreme. The incline of the Wirt is already in pay ore that carries horn silver and chlorides. The tunnel on the Picacho is expected to cut the ledge at a depth of 100 ft, and is now in about 15 ft. Work on these mines will be pushed forward day and night by an ample force of men.

The Hecla.—Messrs. Canady & Vivian have commenced work on the Hecla, and intend to sink to a depth of 50 ft. This is a large ledge, carrying metal from the surface, and promises to be a veritable bonanza. Quite an excitement was occasioned in the district a few days ago by the discovery of a mammoth ledge, traceable for over a mile, and cropping out of the mountain to the hight of 10 ft. The ledge is about 5 ft in width and is heavy mineralized. J. W. Canady and L. Ragle are the discoverers. They expect to commence work on the property in short time.

COLORADO.

Decatur.—Cor. *Colorado Miner*: Last year every one was satisfied to "do assessment work" on their lodes, and to sell at the first opportunity, but now it is our aim and ambition to do all we can to develop a lode, and to hold it until we can sell her smelt or ship our ores, or await the time when a lode can be sold to an advantage That time is not far distant, as we have means to-day to concentrate our ores, and before spring returns we can take ore of high or low grade and have it treated in our town. The Bright Star Silver has finished the boarding house building and assay office, and partly completed their smelter building. Part of their machinery is at the railroad station, and the balance at their works in Decatur. The Captain Jack mine, belonging to the company who own the concentrator, has shut down for the present, but there is some talk of running 200 ft further on their tunnel. The Captain Jack is one of the largest lodes in this district. A wire tramway has been built from their shaft to the concentrator, and buckets filled with ore glide easily down to deposit their load, and thereby hoist the empty buckets, which in their turn perform the same operation. A partial explanation of the sudden interest taken in Decatur is the fact that several rich strikes and big sales have taken place this summer. First the Bond gold discovery made some excitement, and then the rich strike in the Glendale brought things to a fever heat. The former strike consisted of the discovery of free gold in considerable quantities in Warden's gulch. This latter mine found very rich ore at a depth of about 20 ft from the surface. They now have 1 ft of solid ore, said to be worth $1000 per ton. Twenty-three sacks of ore, taken as it was shot down, sold for $2,000, and a short time ago the claim changed hands for the consideration of $300,000.

IDAHO.

The El Dorado.—Cor. *Idaho Statesman*, Oct. 28: There are between 40 and 60 men, we are told, working at this mill and mine, and the managers are in hopes to have it running this fall. This property is of importance to Salmon City, and it is to be hoped that the present management will be productive of satisfactory results. Large improvements are being made.

Mineral Hill District.—This is a new gold bearing quartz camp, which has been mostly discovered this past season, is located on both sides of Salmon river, about 40 miles below this city. There are some over 20 claims taken in it, a number of which are showing well. Wm. Wallace and others are so well pleased with their showings there that Mr. W. is going for the machinery for a quartz mill this fall. One advantage this camp possesses is, the road to it is open at all times from Salmon City, so that work will go on as well in winter as summer, when once in motion.

Boyle Mountain.—Ketchum *Keystone*, Oct. 16: Developments in the claims of Boyle mountain are daily increasing with such favorable, and even surprising results, that experienced miners, and visitors generally, are seized with a confidence that this, independent of every other belt in the country, is rapidly becoming an enormous source of mineral wealth. Reports of new discoveries are continually reaching us, and old locations are being opened up and worked in a manner that indicates a great interest on the part of owners. Supplies are going from Ketchum to the Black Hawk, West Fork and other claims in that region that propose to work through the winter, and it is probable that there will be more doing in the mines of this section during the winter season than in most parts of the country. The Irwin, Niagara and Black Horse are all looking well, and in the Ontario recent developments exhibit a fine body of ore.

The Paymaster Group.—The Philadelphia Co.'s Paymaster group of mines, controlled by R. B. Rogers, have developed remarkably well under the past season's working. The 150-ft tunnel driven on the Paymaster tapped the ledge 150 ft from the surface, and cut a 4-ft ore vein of galena and carbonate character. Besides the large amount shipped here to the company's smelters, about 70 tons, taken from the tunnel and the surface works, remain on the dump. The Iron King, a member of the group, is a mammoth deposit of iron ore, suitable for fluxing, for which purpose it was purchased; but if the veins of galena ore recently discovered in it continue to widen, it will be more valuable as a silver mine. The Bois and Summit, and others of this group, are also improving. These properties are on the east fork of Wood river, nine miles east of Ketchum, and are now reached by a fine wagon road, built this season by the company.

Mill Machinery.—Sixteen wagons, loaded with the last pieces of machinery for the Vienna mill, passed through town yesterday morning. The machinery included a Blake crusher, (weighing three and a half tons after being stripped of movable parts), a large engine cylinder, main shaft, bed-plate, stacks, etc. The teams left Blackfoot on the 23d of September, but have made poor time, owing to bad roads, at one place being compelled to lay over ten days. Upon reaching Galena, derricks will hoist the loads from the wagons to sleds, which are now ready.

MONTANA.

Shonbar.—*Butte Miner*, Oct. 26: The Shonbar are working a full force, and making improvements which will greatly augment the facilities of the mine and increase its ore-producing capacity. The new Dean pump was placed in position last week, and keeps all the levels free from water. A 40-horse power boiler will be put in during next week, which will furnish all the power necessary for the hoist. Ore is now being stoped out from the 140-ft level, which yields 100 ounces in silver and 1 20-100 in gold. The second grade ore from this level produces $86 to the ton.

La Platz.—This mine is being thoroughly explored, and extensive dead work is being done. The high grade ledge in the 250 east drift continues to yield a good output of ore.

Lexington.—The stopes of the 300 continue to supply with plenty of ore the 50-stamp mill, which has not hung up a stamp during the week. Eleven bars of bullion were shipped last week, valued at $17,536.

Mountain View.—At this mine a force of 40 men is employed, principally in drifting and cross-cutting for purposes of exploration and development.

Clear Grit.—In the west drift, 135 ft from the shaft, cross-cutting through a 20-ft ledge of ore, which assays from 20 to 50 ounces. Four months' supply of wood and timbers are in the yard, and a full force, with day and night shifts, will be worked during the winter.

Anaconda.—The new shaft house recently completed is the finest, and, when the machinery is all in place, will be the best equipped, in the district. The foundations for the new hoist are nearing completion. A Burleigh air compressor is being set up. A full force is worked in the stopes, the 200, 300, 400 and 500-ft levels producing ore to keep the Dexter mill running to its full capacity. Five bars of bullion, valued at $7,424, were shipped during the week.

Parrott.—Unusual activity prevails at this mine, caused by the energetic pushing of work on the new shaft house and preparations for the winter campaign. The mine is looking well in every level, stope and drift, and is keeping the smelter running to its full capacity.

New Strike.—Butte *Miner*, Oct. 21: Robert McMinn made a good strike in the Goldflint, owned by himself and John A. Leggat, yesterday. The surfaces croppings of this ledge assayed 200 and 300 ozs, and the owners once aided to drive a tunnel into the mountain to strike the ledge at a lower depth. The tunnel yesterday cut the vein, showing 2 ft of ore, which experts pronounce very high grade. The Goldflint is about 4 miles northwest of Butte, in the corner of Independence district, and at the limit of mineral bearing rock of this region.

A Big Copper Property.—Butte *Inter-Mountain*, Oct. 26: The Liquidator is now conceded to be one of the biggest copper mines in the West, and has already developed a sufficient productive capacity to supply continuously a 50-ton smelter. From the bottom of the shaft, at a depth of 200 ft, a north and south crosscut was run between the foot and hanging walls, and the vein was found to be 50 ft wide, filled with ore susceptible of profitable treatment. In the center of the ledge a level 5 ft wide is now being driven east and west on a streak of ore wider than the drift, and which assays 38 . copper. On the foot wall is a streak of copper glance varying from 1 to 5 ft thick, and assaying 75 . copper. This remarkable rock is not being extracted at present, but there is plenty of it there. One hundred tons of 40 . ore were sold to-day to the Montana copper company. The Liquidator now has on the dump 1,000 tons of ore, assaying 20 . ; 3,000 tons, 15 . ; 100 tons, 40 . , and 10 tons of pure copper glance.

NEW MEXICO.

Burro Mountains.—*New Southwest*, Oct. 21: We can not recall anything strange or startling in the mining world of this district during the past week. Everything pursues the even tenor of its way, the work of development in the young and practically untried mines is continued with vigor, and the number is daily increasing. The outlook is encouraging and everything wears a cheerful aspect; but that is not new, as we have chronicled nothing but cheerful news for months past. There is more work being done in the Burro mountains at present than at any time within its history. A large amount of assessment work is being carried on, exploration is continued, and the great producing mines are turning out copper ore in larger quantities than ever. There were never so many miners employed in the district, and while we cannot encourage miners intending to come here in pursuit of work, still there are very few, if any, habitual underground delvers to be found out of employment in Paschal or Oak Grove. This is, perhaps, the best gauge to go by in approximating the amount of work being done in the camp. The shrill blast of the steam whistle, the crushing of ore and roar of furnaces are heard now day and night at the smelter of the Queen City copper company, at Oak Grove. They have already a great many tons of blister copper, 98 and 99 fine, ready for shipment to Baltimore. It will probably be shipped the first of next week.

Smelter.—We understand that Mr. Hurst is trying to buy an interest in the Shakespears smelter and that if he obtains it he will ship his Victorio ores to that place for reduction.

Atwood.—The Atwood mine, at Shakespears, is now 210 ft deep, and crosscuts are being run to strike the 2 veins between which the shaft has been sunk. The north vein, which has been reached, is 30 ft wide and averages over 20 ozs. in silver, and the south vein, thet has just been struck, averages 40 ozs, and is about 13 ft in width.

Clifton.—R. A. Jackson has purchased from W. F. Clark the Ida, Tilden, Ella, Belle and Cascade mines, at Clifton, adjoining the Copper Queen, and in the vicinity of the celebrated Longfellow. The assessment work has been done upon all these claims, and they are looking well and form a splendid group, being in reality what is often spoken of but rarely seen—a perfect mountain of copper.

Raton Mining District.—*News and Press*, Oct. 28: Considerable excitement prevails over the discovery of gold and silver ore just south of Raton. A large section has been staked off between the bluff east of the railroad and the Sugarite, and even on the plain some very promising prospects are opened. Development work has been lively the past week, and many claim owners are planning to put on a large force to find out what the claims contain. It is still too early to predict what will be the outcome of the district, and although the indications are that discoveries of rich ore deposits have been made, it is better for them to own that the result of the development work be awaited before any general excitement is created. T. Marsh Henderson and Mr. Biddle were among the first to begin work on claims which they staked off and their enthusiasm has enlivened others who followed the example they set. A number of mechanics are so far persuaded of the richness of their claims as to leave their regular work to dig for gold and silver. A week's work and careful assays will tell what the boys have struck.

UTAH.

Christy M. & M. Co.—Silver Reef *Miner*, Oct. 26: Work is progressing as usual on these mines; about 50 tons of ore being extracted daily and sent to the mill. Of the many claims owned by this company, but 2, the California and Tecumseh, are being worked; these two furnishing sufficient ore to keep the mill in constant operation. The Tecumseh has been worked to a depth of 700 ft on the western dip of the vein. At this point the ore body is of good size, averaging 5 ft in thickness, and of better grade than ore found above, proving conclusively that the sandstone silver mines are permanent. About 22 tons of ore are extracted from this mine daily, and the output could be largely increased if necessary. The California is yielding ore from different points, the major part from the 400 level. The same may be said of this as the Tecumseh, that as depth is attained the ore chimneys increase in size and value. The work of exploration is being vigorously prosecuted and attended with results that insure this company a long continuous season of prosperity. Dividends are paid monthly and the stockholders are evidently satisfied with their property, as none of the stock is in market.

Precious Stones.—*Southern Utah Times*, Oct 28: G. Lammersdorf has gone to Salt Lake City, accompanied by P. A. Malloy, to make an exhibit of a valuable collection of precious stones, taken from the Lammersdorf precious stone mines of Southern Utah, which have just been surveyed for U. S. patents. Excitement runs high over this valuable discovery, and next week will bring us fuller reports regarding it.

Frisco.—Everybody thinks that the Cave, Carbonate, Cactus and Comet, an alliterative combination, by the way, are bound to boom, and that '83 will bring a boom for Frisco. The Cave is so big that it is attracting the attention of Utah's best-informed mining men. The Carbonate is opening up such a massive body of lead-silver ore that the present machinery is inadequate for the work it has to perform. The Frisco company talk of erecting new hoisting works of great capacity on the Carbonate and Rattler grounds at an early day, and it is understood that plans are now under consideration by the managers. The Cactus mining company has also purchased hoisting machinery, which is expected to arrive here in a few days, when active work will be resumed upon their valuable property in Copper gulch. This property has just been examined by Alexandre Lancauchez, who gives it as his opinion that immense bodies of ore will undoubtedly be opened up in Copper Gulch.

Russia hopes that her trade with China will be increased by the line of steamers she has recently established between Chinese ports and Vladivostock, her new port in Eastern Siberia. Tea destined for Russia can now be conveyed from Vladivostock by river boats to Irkutsk, which is expected to become the chief mart of the Russian tea trade. Heretofore 35,000,000 pounds of tea have been carried annually by caravan to Kraohta on route to Moscow.

The Denver Exposition—No. 12.

[Editorial Correspondence.]

Directly adjoining Hinsdale on the south and west is

SAN JUAN COUNTY,

From which this entire gronp of five connties derives its name. This connty contains many of the best mines in the San Juan mining region. Galena ores predominate. The heavier lodes are quite productive in lead, hut comparatively poor in galena. The most of the veine also carry gold. The mines are nearly all fissure veins, hoth walls belonging to the same class of rocks—either granite or porphyry, and the ores are nearly all smelting ores, which carry their own flux as in spars and in iron. This county is worth bnt little except for its minerals. Commiseioner J. H. P. Vorhees, who represented this county at the exposition, says there is nothing in it except mineral and fuel—not even a potato can he raised from any of the soil within the county lines, which are quite limited—the smallest, with one exception, in the State. Its area is too high in altitnde for anything except the most limited grazing, averaging fully 8,000 feet above the sea. Its mineral possibilities are, however, very large, as was evidenced hy an exhibit from ahout 100 different mines. Every mountain and other considerahle elevation is fairly rihhed and seamed with veins carrying lead, silver and gold. Many claims, not yet productive, have had considerahle development work done on them; hut nothing like pnshing a mine to its full capacity or prodnctiveness has yet heen done in the connty. Many mines have large qnantitiee of ore on the dumps, ready for transportation whenever it can he done at a reasonahle cost—some up to several hnndred tons. Until the completion of the road to Silverton in July last it was next to impossible to get ores, ont or supplise into the northern portion of the county. Some idea of the difficulties in transportation may he inferred from the fact that one dollar a pound was charged two winters since for packing in supplies to Silverton over the railroad. The price per ton for ores has recently heen materially reduced from their first tariff of $16; but the mines require still lower rates for an economical working of the mines. Silverton is the present railroad terminns and radiating point for supplies to all parte of the county and beyond. Very good monntain roade have heen conetructed, and it is hoped that still further railroad facilitiee will he supplied within a short time.

The Most Notable Feature

In the exhibit of this county was a etack or pyramid of ore in the center front of its epace, which represented great numbers of small hut representative specimens from ahout 100 mines. This pyramid was very artistically arranged, and attracted much attention. Many of the massive specimens in the general exhibit were very rich, and offered arguments in favor of the great value of the mines which could not be resisted. The specimens on exhibition varied all the way from egg size np to two tou lnmps, and reached thonsands in numhers. Excellent coking coal, with coke and coal and timber for building, mining and fnel, were included in the exhibit.

Ouray County.

Directly to the westward of San Juan is Ouray, which is fast coming into prominence as a miuing county. It is located on the Pacific slope of the Rocky mountain divide, and comprises the northweetern portion of the San Juan region. Ite inaccessihility has greatly retarded either proepecting or development there, ae if approached through San Juan county two divides have to he crossed. But a railway ie now projected direct from Denver through Lsadville, or by way of the Arkaneae river through the Marshall Paee over the Rockies. Heretofore it has coet $25 per ton to pack ore to the Rio Grande road, and $10 or $12 more to any furnace for treatment; hut extensive redaction and concentrating works are now in operation within the connty. Ouray ie one of the countiee of which the State may well he prond.

One of the Finest Specimens

Which this county hae sent to Denver is a noble specimen of humanity in the pereon of Governor Pitkin, who took, from the beginning, a deep interest in the inception and carrying ont of the expoeition. The Commiseioner, Mr. F. C. Meyer, aseieted hy Mr. Maeon, also did faithful work in their efforte to advance the material interests of their conetitnency.

Ouray's Pavilion

Was as neat ae any in the building, and occupied a central and quite conepicuoue position. The dieplay therein wae very snperior, hoth in quantity and quality, aleo in classification and general arrangement. It wae appropriately decorated with pictures, and in every way exemplified the good taete of the gentlemen under whose direction it wae constructed and filled. We regret that we have not epace to enter more fully into the details of Ouray's mine and exhibit. Suffice it to say that "ehe did hereelf proud."

La Plata County

Occupiea the extreme eouthwest corner of Colorado, bordering on New Mexico and Utah on the eouth and weet, and eweeping up to the summit of the Rocky mountain divide on the north and west. This conuty is very fortunate in ite variety as well as in the extent and richnese of its resonrces. It lacks only development to occupy a front rank among the producing counties of Colorado. The Denver and Rio Grande railroad passes directly through and opens up the southern and eastern portions of the county. The stock and agricultural resonrcee of La Plata, eepecially in its valleys along the San Juan river and its tribntaries, are very large and important. Vegetahles and frnit do very well in the lower portions of this county, which find a ready market at Pnehlo.

The Area of its Coal Fields

Is very extensive, and hae heen estimated to cover not less than 500 square miles. This coal variee in thickness from 10 to 30 ft., and in some instances ie said to fill a space of over 50 ft. from floor to roof. It lies in two distinct heds, separated hy a layer of iron slate generally ahout four feet in thickness. The extreme southwestern portion of the county was once the

Home of the Ancient Aztecs,

The rnins of whose villages are found throughout an area of ahout 6,000 square miles. These veine are divided in Hayden's reports into three distinct claims: The lowland or agricultnral eettlemente, mostly constructed of stuhhle and adobe combined, the cave dwellings, hewn out of the indurated bluffs, or occupying natnral openings, and third, the cliff houses, or fortresses, mostly huilt of etone, and high up on almost inaccessihle cliffs. These placee were probably used as places of refuge for the inhahitante of the lowlande in times of danger. This region was formerly occupied hy great numhers of Ute Indian tribes, a few of which still linger ahout the agencies. A delegation of theee Indians, some 30 in numher, and accompanied hy one of the sub-Indian agents, visited the exposition near its close, where they formed quite an attraction. They established a regular Indian camp in a portion of the exposition grounds.

The Mineral Exhibit of the County

Was well displayed and cared for under the direction of Commissioners C. D. Wright and John Shepherd. A large numher of mines were represented—not less than 200. In this exhibit was a huge specimen of excellent gypsum from a 40-foot vein nine miles north of Durango; a ton epecimen from the North Star mine; another of same eize from the Red Cloud, hesidee eeveral othere of large eize from various other mines. The veins of this connty carry eilver, some gold, copper, lead and zinc. Some of the mines are very promising, and are reported as yielding well up into the hundreds of dollars on milling prospects. A discovery of carhonates hae recently heen made, which here, as elsewhere in Colorado wherever they are found, is attracting a rush of prospectors. The third largest emelting worke in the State have been erected in Durango, the connty seat of La Plata, and is kept constantly in hlast. Large concentrating worke have juet heen erected on Junction creek, 12 miles from Durango.

DOLORES COUNTY

Made a very fine display. About 150 mines were represented. Rico ie the well-known mining camp of this county, and formed the most conspicuous feature of the exhihit. Dr. J. P. Landon represented the county as commissioner. The oree of this county are mostly silver-hearing, free-milling ores, chiefly from fissure veins in limestone. There are, however, some contact veins between walls of limestone and porphyry, and ore is occasionally found containing so much galena as to require subjection to a smelting process. The Newman group of mines, owned by the Myere Consolidated Mining Company of Denver, carry lead, gold and silver, and are said to run 100 to 500 ozs. of silver, with conaiderahle gold. There are also several other isolated minee which report yields equally rich ae the Newman gronp.

This county also contains vaet coal minee located within eix miles of Rico, some of which ie of a good coking quality. Magnetic and other iron oree are also found in the connty, with plenty of lime near hy for fluxing.

RIO GRANDE COUNTY

Is located on the river of that name where it leaves the mountaine and entere the beautiful valley of San Lnie Park. There are eeveral mining districte in this county, hut the only one that thue far promiees much ie that known as South Monntain, high up in the Summit range—12,000 ft. above the eea level. It ie the richeet gold district in southern Colorado. Ite great drawhacke are eevere climate and heavy enowe; hut the gold ie there. Stamp mille have been erected, a town hae heen huilt, and the miners are there to etay. They have already taken out $1,000,000 or more, and there are many millions yet to he realized from thie one little dietrict.

The diecovery wae at first thought to he eimply a mase of "float ore"—a "elide." Then the whole mountain was coneidered a huge maee of gold-hearing quartz, hut further development hegan to ehow numeroue "veins" in a country of porphyry. The firet discoverere transported their rock eome 200 milee or more for reduction. The Crooke Brothere sent a ten-etamp mill into the district the next eeason, and paid $78,000 for a one-fifth intereet in one of the principal minee—the Little Annie. Other mille were eoon brought in, an English company eending in 50 stamps.

LOS ANIMAS COUNTY

Occupiee the extreme eoutheast corner of the State. It lies on the plain and has no mines of the precioue metale, hut ie rich in coal, iron and bullding etone. The exhibit of this county wae mostly agricultural; but it contained in addition a pyramid of coal in one hody, 14 ft. high. This coal is of good qnality for coking. Iron ore is very ahundant.

Conclusion of the Colorado Mining Exhibit.

With this we conclude our notices of the mineral exhihit of Colorado. We have devoted a large space to thie exhihit, partly hecanse it was large, and in part because we have heretofore devoted perhaps too small a portion of our colnmns to thie important mining region. We have no doubt, the readers of the MINING AND SCIENTIFIC PRESS have appreciated our efforte to give them eo full a description of the mineral development and prospects of a region that has come so suddenly to the front rank as a mining State.

It has been thought and said by some, that the Denver mineral exhihition was merely local in character. Such an expression is neither fair nor trnthful. Of course, Colorado, from the fact that her mines were in the immediate vicinity of the place of exhihit, made the largest show. But the neighhoring territory of Utah, New Mexico, Arizona, Idaho and Montana made each large and creditahle exhihits. Owing to their distance, and the consequent extra coet of transportation, their exhihits were more choice and selected, and lese in quantity. The exhihit was really a show of the States and Territoriee of the Rocky mountains and the great Humholdt hasin. It was not an exhihit of the Pacific coast. True, California and the other Pacific coast States and Territoriee were invited; hut circumstances, well understood, the chief of which was the lack of time to collect and forward suitable displays, prevented the united display, which was so deeirable, and in which all, had circumstances permitted, would have joined with pleasure and profit.

We shall endeavor, in future issues to describe more or less fully the exhihits from localitiee outside of Colorado, and hefore closing shall refer again to Colorado to say something more of her agricultural countiee and their possihilities, also of the city of Denver and its position as a great commercial and railroad center.

W. B. EWER.

A Rock Drill Contest in Cornwall.

A correspondent of the *London Mining Journal* writes as follows:

During the past fortnight Falmouth has heen very lively, caused hy the holding of the Jubilee Exhihition of the Royal Cornwall Polytechnic Society. The rock-drill contest in connection with thie Exhihition came off on Wednesday and Thnrsday, and created a great deal of excitement. Two pieces of stone were provided for the purpose; one a large hlock of Cornish granite from the quarriee of Messrs. Freeman and Sons, Penryn, and the other a large piece of hard tinstone full of joints. The following drills, given in alphahetical order, took part in the contest—the Beaumont, Cornish, Eclipse, Excelsior, and Stephens and Sons. The Barrow drill, although on show in the Exhihition, did not take part in the contest. To prevent dispnte, the order of horing was decided hy hallot, and the drills ran in the following rotation: Stephens and Sone, Excelsior, Eclipse, Cornish and Beanmont, and all ran on a har fixed for the purpose, except the Beanmont in the first day's trial, which having no clamp to fit this har was allowed to work fastened on its tripod. On Wedneeday the conteet was arranged to commence at 2:30 P. M; hnt, from some cause not altogether nnderstood, it was delayed till 4:30. The following tahnlated statement gives particulare of the first day'e running:

	Dia. of cylinder Inches.	Dia. of bit used Inches.	Time of running. Min. sec.	Depth of boring Ft. in	No. of bits used.
S. and Sons	3½	1⅝	8 5	2 2	2
Excelsior...	3½	1⅛	10 0	2 3½....	2
Eclipse.....	2½	1¼	5 50	1 11½....	1
Cornish....	3½	1.13-16.....	8 21	2 4½....	2
Beaumont..	3	1.9-16.....	2 12	Broke down twice.	

From thie etatement it will he noticed that the Beaumont drill broke down twice in the epace of 2 minutee and 12 eeconde. The committee, taking into consideration that it was working at a dieadvantage ae compared with the other drille and it heing late (nearly eeven o'clock), decided to give it another trial on the granite the next day, a clamp to hit the har heing provided for it in the meantime.

The eecond day'e trial wae arranged for 10 o'clock A. M., hut from an unavoidahle canee did not take place till 2:30 P. M. The following givee particulare of running, etc.:

	Dia. of cylinder Inches.	Diameter of bit used Inches.	Time of running. Min. Sec.	Depth of boring—Inches.	No. of bits used.
Beaumont (on granite).....	3	1 9-16	3 0	5¼	1*
Excelsior (on tinstone).....	3½	1⅞	10 7	4½	2
Cornish (on tinstone).....	3½	1⅝	5 20	13	2
Stephens & Sons (on tinstone).	3½	1⅝	10 0	10	2
Eclipse (on tinstone).....	2½	1¼	10 0	16¼	2

*Broke down.

From thie it will he obeerved that the Beamont drill, althongh provided with a clamp to fit the har, again broke down. It is a large and powerful drill, hut a great deal too heavy for ordinary mine work, and eo complicated that ite running alone ehook it to piecee three timee in euccession, so that at last it had to be excluded from the contest. I am informed it broke down in the very same way at the Cardiff exhihition.

One of the committee, Capt. Josiah Thomas, remarked that the horing of the tinstone would he more a test of the tempering of the steel drill hite than a test of the power of the drille themselves, and eo it turned out to he, for both the hits used with the Eclipse drill were completely knocked np, and it eeemed astonishing that snch a stone could be drilled at all with bits in such a etate. For all the drills to be on a par the whole of the hits should have heen tempered hy eome independent emith, ussd to the work, and who had a thorough knowledge of the stone to be bored, hut instead of which, each drill owner had to temper and sharpen his hits in the hest manner possihle. This course placed the drill owners who came from a distance at a decided disadvantage, owing to their want of knowledge of the nature of the tinstone, whilst on the other hand the two Cornish drill ownere were the whole of Tuesday tempering and proving their hits and running their drills at two of the mines near Camhorne, and on this very class of stone. Thie is not as it ehould he, and in future conteets should be prevented hy the committee. The drill owners from a distance were also at another disadvantage, inaemuch as they had to run the drille on show at the exhihition without even the opportunity of a short trial to prove that their machines were in good working order, whilst the owners of the two Cornish drills, although they had drills on show, hronght and ran the two they had heen proving all day on Tuesday. I am sure everyone will agree with me that these irregulariticе ehould cease, and that at all future contests of the kind every drill owner he put on a level. As it turned out, however, the two Cornish drills did not show to advantage, and although, as a Cornishman, I should have heen proud to see them far ahead of their competitors, still it must he done hy having no advantage over their opponents.

In the second day'e running it was arranged hy the committee and agreed to by all the drill owners that each drill should work for ten minutes, when it ehould cease. This was carried out hy all excspt the owner of the Cornish drill, who after running for five minntee and twenty sscouds, called out he would bore no more. When asked for a reason he said he had no more drill hits, which was astonishing, seeing that the day previous he had bored 28½ in. in the granits against 13 in. in the tinstone. Where had the other drill hits gone to? I believe the nature of the tinstone at the moment had more to do with his stopping than the want of drill hits, and so do many others. In the first day's trial there were three men working in and about this drill, against two men to each of the others. This should have been taken into consideration by the committee, and I hope it has.

Now, a few worde ae to the merits of the drille themselves. Having already remarked on the Beanmont drill, which broke down three times in succession, I will pass on to the others. For mechanical merit, ease, and smoothness of working, the palm muet unhesitatingly he given to the Eclipse. From first to last it ran without a hitch, calling forth the praise of all standing round. The working and controlling of its valve arrangement is worthy of remark; the more so when it is considered that although running at a very high epeed, the valve never touches either end of the valve hox. I inspeoted the valve arrangement after the committee, and muet say in justice to whomsoever inventea it, that it ie a masterpiece of mechanical ingennity.

Next in order of merit comes the Excelsior. This is of the valveless type of drills, the only others heing the Darlington and Normandy. It, however, differs from these in that it cuts off the air at half-stroke, delivering the blow hy expansion. By this arrangsment it gets to a great extent over the difficulty experienced in the other drills of its kind—the inahility in getting rid of the exhaust, hut in doing so by cutting off the power at half-stroke, and delivering the hlow hy expaneion, it necessarily followe that its hlow must he somewhat feeble. It also vihratee considerahly during working, which alone is detrimental, as it would he eure to jamh (ae it repeatedly did during the second day'e conteet) in onr very hard and eeamy etone. The interior arrangement ie somewhat complicated ae there are a number of gun metal ringe in segments, and india-rnhher ringe in the bottom cover of the cylinder.

The other two drills, Cornieh and Stephene & Sons, have no peculiar merit of construction. The former has a valve arrangement of the tappet order, ite movements being regulated hy a hlow or hlows from the piston. It also has two screwe to regulate ite feed. It ran fairly well at the conteet, hut from the nature of its conetruction it ie liable to he rendered ueelese at any moment hy either the tappete heing damaged or hroken, or the donhle ecrew arrangement getting jamhed, thus making it very expeneive in repaire.

The Stephene & Sons drill hae a eteam or air-valve arrangement with a etem and brase spiral epring projecting from the npper end to knock the valve over when it sticke or hecomee choked. Thie occurred eeveral times during the trial, and is very detrimental to its effectiveneee; in fact, a eeriee of hlowe had in every inetance to be given to thie projection hefore the drill could he induced to commence work. I have seen a drill hefore with a eimilar valve arrangement in North Wales, and the constant sticking of the valve was a great source of complaint. I hope to hear of thie drill another year when the owner intends to make it give a better account of itself.

All the arrangemente were in the hands of Mr. Jamee Hockings, of Camhorne, and with the exception of the two pointe hefore mentioned, great credit is due to him for the manner in which they were carried out. The compreseed air was supplied by one of Messrs. Hathorn &

Co.'s Reliance air compressors, which ran well and almost noiselessly. There are a number of these in the county giving great satisfaction, which speaks well for their future use. The committee took great interest in the contest, and their decision will be made known on Monday next.

Our Recent Immigration.

Although there has been no rush of immigration to California of late, our population has throughout the entire year been steadily increased by accessions from abroad; and, what is more to the purpose, the people arriving here have for the most part been of the right kind and come from the right quarter, being composed largely of emigrants from the rural districts of the old world or from the Eastern States of the Union. They would in any country constitute a desirable element of the population, and to us, who want tillers of the soil and permanent citizens, they are especially valuable, since the most of them intend to engage in this branch of business, and they all come to abide. These people want homes and are in no sense adventurers. One immigrant of this kind with his family, or even if he is alone, is worth more to the State than a score of gold-seekers, such as came here in former times with the purpose of amassing a fortune as speedily as possible and then going elsewhere to spend it.

For individual miners there is not much to do, unless they are willing to work by the day or are desirous of prospecting. In the older established mining towns, where the mines are being worked, skilled men can get employment. New men coming here to prospect, however, will do best, perhaps, in the south-eastern part of the State. Mono, Inyo and San Bernardino counties offer fields for prospecting. In the northern part the land is more settled, though there is still room, of course, to prospect. Prospectors, however, must expect to have means for maintainance aside from their occupation.

For grain raising or purposes of general farming it makes but little difference what part of the State a man locates in, so long as he keeps in or to the westward of the lower foothills of the Sierra Nevada, and within easy reach of market; though, even here, certain localities will, on account of soil, water, etc., be found especially well fitted for particular branches of the business. The climate of the great interior valleys, and even at the same altitude throughout the coast tier of mountains, is much the same from one end of the State to the other, the mercury in winter ranging only a few degrees lower at the upper end of the Sacramento valley than it does in San Diego county, 500 or 600 miles farther south. Garden flowers bloom throughout the winter and oranges can be grown in the open air in either of these localities. The settler, so he avoids the extreme northern and the mountain and desert districts of California, will find no great choice between other portions of the State; coming from almost any other part of the world, to him both our winter and summer climates will be likely to prove acceptable.

In commencing living in California, it is possible for the beginner, if his means are limited, to economize in the matter of building to an extent not practicable in countries having long, cold winters and rainy summers. A very cheap sort of house can here be made to do for a few years at first, scarcely any harm at all being needed. The poor man can, if needs be, make shift to live in a board shanty or a canvas covered hut, a shed, closed only on the sides from which the heavy rains come, affording all needed shelter for his cows and work animals. Some of the largest land owners and most prosperous farmers in the State began their careers in this way, having lived with their families in the covered wagon with which they crossed the plains or in a tent pitched beside it for a year or two at the start.

THE GULF STREAM.—Commander Bartlett, of the English Coast Survey, has been investigating the Gulf Stream, and last week at Montreal he gave some of the results of his work. He made havoc among certain generally received ideas concerning that famous current, which, he says, does not flow out of the Gulf of Mexico, nor over a bottom channelled with ridges and valleys parallel with the Appalachian system. He says that there is a wide plateau extending along the coast from the Bermuda Banks, over which the Gulf Stream flows, sweeping it clean to its hard coral bottom. Beyond this the bottom slopes rapidly downward, and is ooze with the wash from the plateau. The stream is not a river of warm water flowing over cold, and the Arctic current does not run inside. This will be all new to most people, and especially to those whose ideas of the Gulf Stream are indefinite anyway. Perhaps a fact which will interest these people most in connection with the matter is the tribute Commander Bartlett paid to Yankee ingenuity at the meeting referred to above. Dr. Carpenter having expressed his admiration of the work added that it pleased him to know that the results were obtained with British instruments. To this Commander Bartlett replied that Sir William Thompson did invent an apparatus and kindly forwarded it to the Coast Survey, but it would not work. Yankee ingenuity then invented an attachment by which it was made so efficient that soundings of 3,000 fathoms can be made in 30 minutes and without deflecting more than a fathom from the perpendicular.

Useful Information.

A Difference in Electric Currents—Some Not Dangerous.

Mr. Ladd, of the District Telegraph Co. of this city, in a recent letter to the *Bulletin*, while speaking of the difference in electric currents, says:

Every electric current, however produced, has two qualities: First, "intensity," which we denominate "electro-motive force" or the power of overcoming the resistance offered to its passage through conductors; second, "quantity," or the volume of the current generated without regard to its "intensity." For example: A stream of water an inch in diameter, with a fall or pressure of 100 ft. in a mile, will run at the same speed (friction disregarded) and press against any obstacle with the same pressure as the Mississippi river with the same fall or pressure. In the Edison system of lighting by incandescent lamps the circuits are so arranged that the "intensity" of the electric current generated for one lamp is sufficient for all the lamps in the district, regardless of the number, but the "quantity" or volume of a current must be in proportion to the number of lamps. Therefore the "intensity" of an Edison current is fixed at 110 "volt"—the "volts" being a term used to indicate the electro-motive force of a current. Somewhat as "pounds" are used to indicate the pressure of steam or water, 110 "volts" is only about the force of the strongest current used on the Western Union wires, and the shock would be no greater. Indeed, Mr. Edison has frequently taken the whole shock from his largest generator of 250 horse-power without the least personal injury. But the current used to operate "arc" lamps of the standard size used in the streets of San Francisco and other cities is from 46 to 60 "volts" *to each lamp*, and as 40-light generators are generally used, 40 lamps are placed upon each circuit and the "electro-motive" force on such a wire is therefore from 1,840 to 2,400 "volts;" 1000 volts is sufficient to produce instantaneous death, and where the current is transmitted in waves, as is the case, practically a smaller number of volts would be fatal. The British Parliament has recently passed an act prohibiting the introduction into buildings of any electric current exceeding 300 volts, within which limit no danger of fire or personal injury is apprehended. The San Francisco Electric Light Company, which is soon to introduce electric lighting in this city on a large scale, will use the Edison current, which will consist at most of only 110 volts, which is only equal to the strength of the current used by the Western Union Telegraph Co., and is perfectly harmless.

PAINTING ON SILK.—Some years ago an artist of Florence employed a method of painting on silk and other fine fabrics in such a way that the surfaces of the colors were not damaged when folded or rubbed. His paintings, even when subjected to tests far more severe than such crumpling as ordinary wear would produce, are said to retain their appearance unchanged, the colors remaining as bright and the surface as smooth as when first laid on by the brush. The method is now no longer the complete secret it was, as the medium is at present manufactured for amateurs, though protected by patent. An example, consisting of groups of flowers painted on blue satin by this Adolfi process, shown by Mr. Emil Dunki, has been subjected to hard rubbing, without there being any appearance of injury to the painting. Some Italian artists have tried the medium for oil-painting on canvas.—*Land and Water.*

WHAT BECOMES OF THE OLD WIRE CABLES.—The new wire cable recently laid on the western division of the California Street railroad was manufactured in this city. The cable which it replaces was of Eastern manufacture, and was made of Bessemer steel. It had been in use 13 months. The cables made here have exhibited various degrees of quality of endurance. One lasted 20 months; others have worn out in six and four months. Formerly the old cables were shipped to Japan, where they were converted into tacks and other manufactures, but the market becoming overstocked some of the cables are now cut into short lengths and utilized in the hydraulic mines, where they are used as guys for derricks.

GRADING ON A VOLCANO.—The Idaho *Statesman* says: "The activity of volcanic action in the Snake river lava beds, near the line of the Oregon Short Line railroad, is driving many of the graders from the work. In an area of about 22 square miles, at short distances apart, smoke and flames of peculiar odor, color and shape issue from the chasms and seams in the lava. The irritating sulphurous vapors in themselves cause many to quit work, while the unusual agitation of the boiling springs and the general commotion all over the fields of lava has caused a superstitious fear to take hold of many of the railroad hands, and they are leaving the section terror stricken. The whole area has the appearance from a distance of being on fire."

A NEW GLASS, transparent and more brilliant than common crystal, but containing no silex, potash, soda, lime or borax has been invented by a chemist in Vienna. It can be cut and polished, and when fused adheres to iron, bronze and zinc.

UTILIZATION OF OLD CASTINGS.—Mr. F. Becker of Neuss, Germany, wishing to utilize an old casting that was too large to take to the cupola and could not be conveniently broken up, hit upon the expedient of building a furnace against it and tapping it off on the spot. Carefully covering the mass of refractory material to prevent the radiation of heat, he lighted a coke fire at one corner, and as soon as that portion melted ran it off into a ladle, and by repetition of this process with the other corners the casting was reduced in size until it could be moved without much trouble. It would seem that there must have been local circumstances preventing the use of dynamite to reduce the casting to smaller pieces, since if this was not the case it would appear that an unnecessary amount of labor had been expended in achieving the end aimed at.

A NEW TEST FOR GOLD LEAF was accidentally discovered at the Farrell Venetian Art Glass Manufacturing Company's works, in Brooklyn. By the Farrell process the leaf is placed on the incandescent glass, which is then blown. The expansion splits the leaf into beautiful and fantastic forms, and the object is then fired. In using a guaranteed .999 quality of gold leaf the workman found that the expansion separated the gold from a copper alloy, and the object was ornamented with gold and a handsome green, the latter color being due to the oxidation of the copper.

GETTING RID OF STUMPS.—In the early autumn or winter bore a hole one or two inches in diameter, according to the diameter of the stump, and about 18 inches deep. Put in it one or two ozs. of saltpetre, fill the hole with water and plug it close. In the ensuing spring take out the plug and ignite it. The stump will smoulder away, without blazing, to the extremity of the roots, leaving none but the ashes.

IRON AND WOOD may be joined with the following composition: Fine Russian isinglass is dissolved in strong acetic acid (pyroligeneous acid) until the consistance of a strong firm glue is obtained.

Good Health.

ALCOHOL AND THE SICK.—If it is true, as we are assured by eminent scientists, that alcohol is not food, but a virulent poison, never digesting and becoming a part of the body, like food, but is ever at war with every fiber and function of the human system, leaving it as pure alcohol as when it entered, thrust out as a foe and intruder, I have no philosophy to explain how it can act favorably upon the sick, who have less power of resistance, simply because we call it *medicine* instead of "grog." If it always retards digestion, as we are told by the best authority, I cannot see how it can aid the digestive powers of the sick. If it increases the toils of the heart, to the amount of lifting from 18 to 24 tons in a day, and if the heart is the main spring, the most important motor of the body, it puzzles me to see why it should be given in "heart disease," when that organ is in a debilitated state, scarcely able to perform its ordinary functions. If it irritates the nerves of the robust, I see no reason to infer that it will quiet the sick. If it weakens the healthy, gradually undermining the system, to me it seems false philosophy to suppose that it will "tone up" and strengthen the sick. If, in common with all stimulants—chemical, poison, and not food stimulants, having a basis of nutrition—if such stimulation tends to increase action by an undue rousing of vital force, a waste of power, always followed by a reaction and consequent weakness, I am not able to discover a reason for its use by the sick, who have no strength to spare. If this is "a good creature of God," it has some remarkable peculiarities, strange freaks, if the popular notions are correct.—*Dr. J. H. Hanaford.*

CLEANLINESS.—If "cleanliness is next to godliness," filthiness renders one incapable of reaching the highest type of spiritual growth. Cleanliness is naturaly favorable to the best development of our physical, mental and moral natures. Filthiness is accidental, and wars against our highest welfare, while the sun, air, water and other natural forces are harmoniously laboring for the removal of the filth, which necessarily results from breathing, decay, combustion. We may learn important lessons, may learn to breathe clean air, eat clean and wholesome food, keep the body clean, thus avoiding the influence of filth to dwarf the body, stultify the mind and contaminate the soul.—*Dr. J. H. Hanaford.*

THE MEDICAL PROFESSION.—There is no department of human effort and study that is held in a higher degree of honor at the present day than the medical profession; nor is there any other that contributes more materially to the happiness and welfare of mankind. To noble minds there has always been a great charm in the pursuit of the healing art, and it has been the chosen study of some of the most brilliant minds that have made their mark upon the history of the world. In this new world the science of medicine has outgrown many of the trammels that bound it in the old, and year by year its resources become richer and more varied, and its capabilities greater. To what ultimate pitch of perfection it may come it is not given to man to forsee.

BITTEN BY A TARANTULA—Louis Gurado, an Italian fruit vender, who keeps a stand at Second avenue and Fourth street, was bitten on Saturday by a tarantula, and was nearly frightened to death. He was in the act of cutting a banana from a bunch on his stand, when the insect, which was evidently hidden on the stalk of the bunch, stung him on the right thumb. Gurado struck at the insect and killed it. Soon after he felt a sharp pain in his thumb, began to feel dizzy and uncomfortable, and in a few minutes fell on the pavement like a man under the influence of liquor. His hand and arm swelled to nearly twice their natural size, and the swelling increased and communicated to his face and neck. His wife, who was with him at the stand, became alarmed and cried out that her husband was dying. A crowd collected about the man, and this attracted a policeman. An ambulance was summoned, and Gurado was sent to Bellevue Hospital. When he arrived at the hospital the swelling had already begun to subside. A cooling salve was applied to the wounded thumb, and yesterday morning, having fully recovered, he was allowed to go to his home.—*N. Y. Times*, October 9th.

EXERCISE AND REST.—Exercise can kill as well as cure. To be taken advantageously, it should be done with judgment. Sometimes a particular part of the body needs exercise, but the whole body is too weak to give it. In such cases only the part needing it should have it. But there is one rule which is applicable to all—never go against the instincts. Many persons have hurried themselves into the grave by endeavoring to "keep up" when they ought to be in bed; and they do keep up, too, for so long a time that when they take to their beds their strength is so completely exhausted that the system has no power to rise, and they fall into a typhoid condition and all is lost. When anything serious is the matter with domestic animals they court quietude and perfect rest. Sometimes we feel indisposed to exercise from sheer laziness; in all loose conditions of the bowels, debility, an instinctive desire to sit down and stay there, is universal. In most of such cases quietude is cure. But there is one safe cure for all under all circumstances; if every step you take is with an effort, do no take another—go to bed; if you feel the better for a walk, then walk, but stop short of great fatigue.—*Dr. W. W. Hall.*

PNEUMONIA AN INFECTIOUS DISEASE.—That acute lobar, croupous pneumonia is considered by some an infectious fever, with evedint tendency to the lungs, or as now better expressed, a zymotic disease, caused by the inhalation of bacilli, which accumulate mostly in a lower lobe of one lung, we have often had occasion to note. The proofs of this statement accumulate daily. Dr. Kohnhorn found that the disease had become epidemic in one of the barracks at Wisel. Occasionally it broke out as a local epidemic. The regiment stationed there had suffered frequently from the disease. Not a year passed without many falling a victim to pneumonia. The regiment was then placed in other quarters, and no further case happened in this regiment. The barracks were torn down, the soil disinfected most thoroughly, as also all the building material. Since the regiment has been camping in these rebuilt barracks not a solitary case of pneumonia has made its appearance.—*Medical and Surgical Reporter.*

CHILDREN'S CHANCES OF LIFE.—An English writer on vital statistics calculates that of ten children born in Norway a little over seven reach their 20th year; that in England and the United States somewhat less than seven reach that age, while in France only five reach it, and in Ireland less than five. It is also ascertained that in Norway out of 10,000 born, rather more than one out of three reaches the age of 70; in England one out of four; in the United States, if both sexes be computed, less than one out of four; in France less than one out of eight, and in Ireland less than one out of 11. Further, it appears that in Norway the average length of life, or the effective population, is 39; in England, 35½; in France not quite 33 years, and in Ireland not quite 29.

IS OBESITY A DISEASE?—Obesity, some of the French physicians claim, is a disease of the cellular-adipose tissue, and must be treated as such. It begins by fatty accumulations at normal points, whence it gradually makes its inroads on health and beauty. It first commences externally, and afterward presses from within so as to finally give rise to serious disturbances—obstruction of the lungs, palpitation of the heart, dyspepsia, lack of red corpuscles and of blood sufficiency, and some of the most nervous symptoms of trouble. The greatest point of danger is the heart, which is sometimes quadrupled in size, and filled with dark, jelly-like substance. Out of 57 people examined after death who were obese, 50 were found to have dangerous heart disease.

DEATH FROM SEA SICKNESS.—A recent Boston paper states that a gentleman, whose name is not given, but who is said to be well known in the Western States and connected by marriage with the late Congressman, Thos. Allen, of St Louis, after spending a few weeks at Nantucket, accompanied by his family, joined a fishing party, and while on the excursion had a violent attack of sea sickness, which passed into convulsions, in which he died.

Passing Events.

We note from the local interior journals that the water season this year is a good one, and that most of the mines expect good results. The abundant rains of the past few days will augment the volume of the streams and water courses in the mountains.

Just at present local mining news is somewhat scarce in this State, owing to the interest in politics prevanting the journalists gathering their usual memoranda.

We note elsewhere the presence in this city of the biggest bar of gold ever made in the world.

Up in Idaho in the region about Wood river, prospecting has pretty much ceased, on account of the cold weather. In parts of this State, Southwestern Nevada, Arizona and New Mexico that sort of work can go on all winter.

The Colorado Atlantic & Pacific tunnel, an illustrated description of which we gave two weeks ago, has struck what appears to be a very rich vein of ore in their heading. This body of ore, according to the *Colorado Miner*, is believed to be the "Diamond Joe," an extension of the Great West lode, which has, for some time, been a very rich and productive mine. This is believed to be but the beginning of the end for this mammoth entarprise, which, it is thought, will soon become a large and steady ore producer, and do much to establish more firmly the theory of deep paying mines in Colorado. The tunnel will soon reach a point of from 1,500 to 2,000 feet in depth from the surface.

A Big Gold Bar.

We saw this week, at the Bank of California, in this city, the largest gold bar ever cast in the United States. It was shipped to the bank by the North Bloomfield (hydraulic) Mining Co., of Smartsville, Nevada county, Cal. The valne of the bar is $114,000, and weight 511½ pounds troy. Its length is 15 inches, width 6 inches and depth 7 inches. It contains 630 cubic inches of gold, and is worth about $19 per ounce.

The mold for this bar was cast at the Nevada foundry of George G. Allen, Nevada City. The entire dimensions of the mold are as follows: On top, 17 inches long and 7 inches wide; on bottom, 16 inches long and 6 inches wide. It contains 715 20-100 cubic inches. The thickness of the sides is ¾ inch and bottom one inch. The mold weighs 138 pounds, and was cast expressly for making this bar. The castings were from iron produced at Clipper Gap, in this State.

The North Bloomfield mine, from which the gold came, is one of the most prominent hydraulic mines in California. The run is not an exceptional one, though the bar is. The line of the tunnel is cleaned up about twice a year, and this time they thought they would see what they could do in the way of casting a big bar. The bar is said to have been the result of a 20 days' run.

It was in 1873, if we remember aright, that the Spring Valley Mining company sent down to this city a bar weighing 141 lbs , worth $41,000. At the time they thought this the largest bar ever made, but at their request we made inquiries and found that Seligman & Co., bankers, of this city, had received ore from Helena, Montana, worth an even $50,000; the London and San Francisco Bank had one worth $35,000, and the Mint and Bank of California had each had one worth $40,000. The San Francisco Assaying and Refining company had also had one worth $41,000.

The Spring Valley people then went to work, and after 35 days' run, with 1,000 in. of water, with a partial clean up of 800 ft. of head flume and 14 under-currents, produced a bar worth $71,273.15, weighing 299 lbs.

Since then, however, the Spring Valley mine, Cherokee Flat, Butte county, shipped to this city a gold bar valued at about $90,000, and that was considered an exceptionally large one. The North Bloomfield company, considering it owned the biggest hydraulic mine in the State, thought it would make the biggest bar, with the result noted.

There is no special advantage in making bars so large, except in happening to have the gold to do it with. Smaller bars are more convenient to handle, and some people even prefer the metal in small circular shape, such as we are accustomed to see on bankers' trays. The big bar we refer to is on the way to the Mint, out on Fifth street, where it will soon be transferred into coin. The North Bloomfield and the Milton hydraulic mines, both under the same management, have produced this season about $1,000,000 in gold, and the ground they are in is increasing in richness right along. This doesn't look much as though hydraulic mining was a dead industry.

The Lincoln Coal Mine.

One of the most promising and important industrial enterprises of which Placer county can boast is the development of coal fields in the western part. It will be remembered that the old mine was closed some few years ago, owing to various difficulties in obtaining the article in paying quantities. Within the past two years, however, the enterprise has taken a new start, this time in the old Cook place, and about half a mile northwest of the old mine. Here the best coal is found in large and paying quantities, the bed being about seven ft. in thickness, and apparently inexhaustible. The mine is owned by Mr. John Landis, of Wheatland, and is under the immediate superintendence of his brother, Mr. James Landis. About 25 men are employed, and the mine is run day and night, about 50 tons being extracted daily. Recently a new shaft has been sunk 150 yards northeast of the one in operation at present. This shaft is about 100 yards from the California and Oregon railroad, and a switch will connect with it. The new mine will have double the capacity of the present one, with an improvement in the shape of a large 1000-ton bunker. The demand for this coal is far in excess of the supply, and is daily increasing. It is used in hotels, flouring mills, for steam purposes generally, and as a substitute for firewood generally.

Hudson River Tunnel.—Work on the Hudson river tunnel is being steadily pushed forward, and the large air compressor now building for the tunnel by the Clayton Steam Pump Works of Brooklyn, N. Y., (three of whose compressors have been used since the commencement of the tunnel), will be placed in position and working at the foot of Morton street, New York, in a few days. This air compressor is of the Clayton Improved Duplex pattern, having two 22-inch diameter steam cylinders, two 24-inch diameter air cylinders, and 30 inch stroke. It is 20 ft. in length, 10 ft. in width; weight 25 tons; and its working capacity is 3,750,000 cubic feet of air per 24 hours.

Explosion of the Eureka Accumulator.

An accident occurred on Sunday last at the Logan shaft of the Eureka Consolidated Mining Co., Eureka, Nev., the accumulator of the new pumping machinery bursting into fragments and doing considerable damage to property, but injuring no one.

These pumping works are on the hydraulic system, now so successfully operating at the Combination shaft, on the Comstock. The new machinery has only been in operation a couple of months and was working smoothly. It was started up and kept running some time under the personal supervision of Mr. Joseph Moore, Superintendent of the Risdon Iron Works, acknowledged to be one of the very best mechanics on the coast.

The explosion is a very curious one and deserves more than passing mention; as the mining community is interested in the hydraulic system of pumping, and as it may be thought that this accident is due to a fault of the system, a brief explanation will be necessary. Suppose the mine is 1,000 ft. deep, and that the water is to be raised that distance. Upon the 1,000 ft. level is erected a pair of hydraulic pumping engines, which received their pressure water through supply pipes from the surface. By these two pumps the drain water is raised through the discharge column, and the water used in doing the pumping is sent back through the return pipe to the reservoir on the surface. On the surface is a cast iron accumulator partly filled with water, the remainder of the space being filled with air. This air is kept constantly at a certain pressure by means of plunger pumps which in turn are operated by a steam engine. These pumps supply the accumulator with water and keep it on a pressure great enough to move the two underground pumps. This in brief is the principle.

It was this accumulator which exploded. The accumulator had been tested up to 2,000 lbs. to the inch, but was only carrying 1,150 when it exploded. From the local paper, the Eureka *Sentinel*, we take the following concerning the disaster:

The accumulator burst about 30 ft. below the cap, two sections of 10 ft. each and the base below remaining intact. The theory is that the explosion took place at the line where the air and water met. About 20 ft. of the accumulator went into pieces, varying in weight from some 1,800 pounds to an ounce or half ounce avoirdupois. The eastern portion of the works, as mentioned, was broken down and completely wrecked. Eight large missiles went through the building, the two principal of which through the south and east ends. The loss to the woodwork is estimated at $3,000. The cost to replace the part of the accumulator destroyed will be probably somewhat between $10,000 and $15,000. The total loss, to put everything back in smooth running order again will not exceed, and will not be likely to reach, $20,000.

The cause of the explosion is totally unaccountable; it is a mystery. Each separate section of the accumulator had been tested up to 2,000 pounds to the square inch. It had been run before for weeks at a time under a pressure varying from 1,150 to 1,200 pounds, and it has been subjected to a pressure of 1,400 pounds. At the time of the explosion the pressure was 1,030 pounds, according to the testimony of the engineer, Mr. Boston, who is a remarkably careful man, and his statement is doubtless correct, for there was no occasion for any greater pressure than was on. As mentioned, the point of explosion was in the second and third sections from the top, above the water line. This is evident from the fact that these were torn to pieces and hurled to great distances, while the four lower sections and the top section merely fell off, and were found near the base of the accumulator. What renders the explosion difficult to account for is that the material of which the accumulator was manufactured was of the very best—cast out of 25 per cent. steel and 75 per cent. of the first quality of pig iron, the breaking strain of which mixture was 33,000 pounds to the square inch.

The fragments thrown off were found upon close inspection, to be of the best quality, without defect or flaw anywhere. Tested with the chisel the mixture cuts as wrought iron, and, being struck with the hammer, leaves a smooth, polished impression. The only defective place discovered was near one of the flanges, and was not broken by the explosion, but the fall. This accumulator, according to relative pressure, is 25% stronger than the one in use at the Combination shaft on the Comstock, the latter being of iron entirely. This statement makes it clear that the explosion was caused by some unknown force, the agency of which is yet to be determined.

The impression seems to have become general that the explosion of the Eureka Con.'s accumulator is a great disaster, and that it will be a long time before the damage can be repaired and work resumed. This is not the case. In a conversation with Mr. Thompson, we learn that the damage done can be repaired in 60 days, at the cost given above. Of course arrangements will be made at once to have the accumulator rebuilt without delay. There is no reason apparent why the explosion occurred, and that there should be a second explosion is not to be calculated on. The rise of the water in the shaft is nothing, as it runs over into the tunnel at the 850 level, and can be all pumped out in 10 hours.

Smelting in the Flintshire Furnace.

This style of furnace is sometimes used for rich galena ores assaying from 75 to 80 per cent. of metal, and occurring in a gangue of calcite flour spar and pyrites. In those localities where it is used, the ore, having been carefully separated by dressing operations from the gangue, with which it was originally associated, is charged upon the concave bed of the furnace immediately after the working of a previous charge and while the furnace is at a dull red heat; for its temperature has fallen considerably during the tapping out of the metal and the withdrawal of the slag produced from the previous charge. This Flintshire furnace is of the reverberatory type, having the fire-grate, a, (see engraving) at one extremity of the bed, from which it is separated by a hollow fire bridge, b, of from 18 to 24 inches in width, while the other extremity of the bed communicates by two openings or flues, g, g, with a larger flue which conveys the gases and lead fumes to a stack some 60 feet in hight. The arched roof of the furnace is kept very low and slopes from the fire-place to the flue end, and at a point near the middle of its length it is perforated by an aperture, c, over which is suspended a hopper, o, into which the charge is introduced, and then allowed to fall, when required, through the opening in the roof upon the bed of the furnace. The furnace is supplied with three doors, h, h, upon each side. Through these, at the front side, the charge is rabbled, and the lime introduced as required towards the conclusion of the operation; while through those at the back side of the furnace, the slag is withdrawn after tapping out the metal. At the same time the several doors serve for the admission of air at intervals during the first or roasting stage of the process; and likewise at the close of one operation, the doors are opened to cool down the furnace previous to the introduction of the succeeding charge, which object is further controlled by dampers placed in the flues at the end of the bed. Immediately below the middle door, on the front side, is placed the tap-hole for drawing off the metal from the well of the furnace into the iron pot, m, placed outside for its reception, and known as the lead pot, or lead kettle.

The fire-grate is only supplied with one door used for the introduction of fuel to the fire, and which opens to the back or laborer's side of the furnace; while over the ash-pit, in front of the fire-hole, is built a short flue for carrying away any vapors passing in that direction during the roasting. An arched vault, f, runs the full length of the bed, communicating with the atmosphere at both extremities; and upon this is built a course of brickwork known as the *cramp course*, upon which again is laid the brickwork, forming a concave hearth, approximately of the form of the working bed, which slopes from the two ends towards the tap-hole, as also from the back towards the front; so that the metal, as it is reduced, collects in a kind of well over the tap-hole, at the *front* or *working* side of the furnace; but the working bottom of the furnace is formed of *grey slag*, the product of the working of the furnace itself, the slag being broken up and introduced into the red-hot furnace, where, after melting, the furnace is allowed to cool down again until the slag assumes a semi-fluid or pasty condition, in which state it is passed over the bricks by means of rakes, paddles and bars, into a layer of from 6 to 12 inches in thickness and of the form required to be given to the furnace bottom, after which it is left to solidify as the furnace cools. Such a furnace bottom requires about five tons of slag for its formation. The masonry of the furnace is braced together in the usual manner by stays and tie-rods; while, in some cases, the exterior of the furnace is formed wholly of iron plates, tied together by iron bolts or tie-rods.

The exact course pursued in the smelting of galena in this furnace, and the precise method of manipulation observed in the conduct of the process, differ in their detail as carried on at the different lead-smelting establishments; as also at the same establishment upon a slight variation in the composition of the ore, especially with regard to the amount of quartz or of lime left associated with the galena; but generally the charge employed weighs about 21 cwts., besides a small amount allowed for draughtage to compensate for the moisture in the ore. This charge, as previously stated, is introduced from the hopper above the furnace, into which it is first delivered, on to the red-hot bed of the furnace, when the first stage, or *calcination of the ore at a low temperature*, commences; for which purpose the charge is kept upon the raised part of the hearth of the furnace above the well, the doors being left open for the admission of air, while the temperature is carefully regulated by the damper in the flue end, so as to raise the heat as high as possible, without fusing or clotting the ore. To prevent the latter, and, at the same time, to present fresh surfaces to the oxidizing influences of the air, the charge is kept continually stirred or rabbled. This (calcination) stage continues for from one and one-half hours to two hours, and at the end of this time the temperature of the furnace is raised by adding more fuel to the fire, and so exposing the charge to a higher calcination heat, care being taken that the temperature does not increase sufficiently to melt the charge. The effect of this calcination is to oxidize a portion of the plumbic sulphides to plumbic oxide and sulphate, so that in the next or melting stage,

when the doors of the furnace are closed and the damper raised, whereby the temperature of the furnace is raised still higher in order to melt the charge, which then runs down into the well of the furnace, attended by a kind of ebullition from the escape of gases, due to a partial reduction of the lead by the reaction of the undecomposed plumbic sulphide with the oxidized products formed during calcination. A few shovelfuls of slaked lime is now thrown into the furnace, in order to stiffen the mixture of slags and undecomposed ore, which is then raked onto sloping sides of the bed, where it solidifies somewhat, and is then broken up and exposed during about an hour to a further calcination, upon the completion of which the heat is again raised and the charge melted down with the same decompositions as occurred in the previous melting stage of the process, and by which a further portion of metallic lead is separated. The operation of stiffening or setting up with lime, followed by another calcination, if again this is repeated, but for a shorter period than before, after which the charge is again melted down, and the slags finally thickened or dried with lime, pushed back on to the higher parts of the bed, and the lead allowed to drain from them into the metallic bath below.

The furnace is now tapped into the lead kettle, and the slag, known as "grey slag," is withdrawn in pasty lumps through the back doors of the furnace.

A quantity of coal slack, along with a little live coals are thrown upon the surface of the metal in the lead kettle, and are well mixed with the metal, by stirring the mixture with a perforated ladle; after which the metal is skimmed, and the skimmings containing sulphur, sulphides of lead and iron, with small particles of unreduced ore, are returned to the furnace with the next charge.

The slags, as will subsequently appear, are rich in lead and oxidized compounds of lead. Since in the third stage, or setting up with lime and recalcination, it is the practice to produce a larger proportion of the oxidized compounds of lead than is necessary to react upon the undecomposed sulphide, hence an amount of lead escapes into the slag as oxide and sulphide, the former probably in combination with silica, derived from the materials of the furnace, etc.

The whole operation of working off a charge in this furnace occupies from five to six hours, with a consumption of about 12 cwt. of coal per ton of ore, and the production of about five cwt. of grey slag. The slag is the subject of a further treatment in the furnace known as the slag hearth, for the more complete separation of its lead.

The action of lime in the above operation has been the subject of much speculation; and while it is asserted by some metallurgists that its addition affects the decomposition of plumbic oxide, calcic silicate and calcic sulphate, yet these reactions appear doubtful, so that its chief use would rather appear to be to thicken or prevent the too great fusibility of the slags, permitting, thereby, of their better exposure for the oxidation of the plumbic sulphide in the calcination following the setting-up stage.

The gray slag is not always fused, the presence of foreign materials in the ores largely determining the fusibility or otherwise of the slag. Thus any zinc present in the ore as blende is not reduced during the smelting, but continues to accumulate in the slag at each stage of the process, and in which it is finally removed from the furnace, except such proportion as may be volatilized during the smelting process; and the alumina, also, present in the ore accumulates in the slag as the reduction proceeds, while, as above stated, slag also contains a large proportion of the oxidized compounds of lead.

The method of lead smelting in the Flintshire furnace, as above described, thus comprehends four distinct operations:

1.—Calcination of the charge at a low, red heat, whereby a certain amount of plumbic oxide and sulphate are produced.

2.—Raising the temperature so as to melt the calcined products, thereby effecting a reaction between the above oxidized compounds and the unchanged ore, whereby a large proportion of the lead is reduced.

3.—Setting-up with lime, and the reduction of any residual sulphide; together with the formation of a larger proportion of oxidized compounds of lead than is required to effect the reduction of the plumbic sulphide.

4.—Tapping out the reduced lead, and subsequent withdrawal of the pasty lumps of grey slag.

In New Mexico as elsewhere very prominent causes of failure have been the erection of machinery in camps as yet unable to furnish ore in sufficient quantities, or to furnish ores adapted to the works, the erection of mills upon properties imperfectly developed, and the erection of crude, ill-assorted machinery, not capable of treating satisfactorily any ores at all.

The New York *Mining Record* reports good mining properties in demand, the inquiry daily increasing, and more and more a disposition to invest where there is a reasonable prospect of developing a valuable deposit of ore for the purpose of obtaining dividends.

W. J. Madden, of Smartsville, has resigned the superintendency of the Golden Gate Hydraulic Mining Company, in which capacity he has served for the past four years, having charge also of the Nevada Reservoir Ditch Company's property.

The Philosophy of Fluxes.

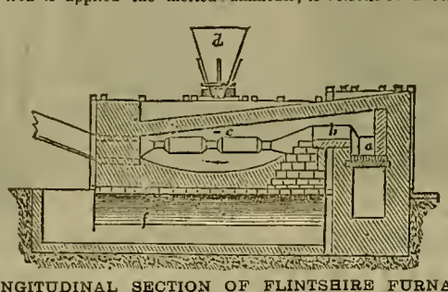
A series of articles is now in process of publication in *Iron* on the "Rational and Practical Metallurgy." The latest number received treats upon the philosophy of fluxing, as follows:

The rationale of fluxing brings us face to face with a wide-spread popular fallacy that has remained undisturbed and unrefuted (so far as we know) by any of our teachers of modern science. Workmen generally believe that by adding what is called a flux to a melted or melting metal, the metal is made to melt at a lower temperature, or that being melted, the flux renders the metal more fluid.

If this were really the case, it would be a very remarkable fact, well worthy of scientific investigation. It would disturb all our tables of fusing points and the prevailing scientific doctrines of the relations between the solid and the liquid states of matter.

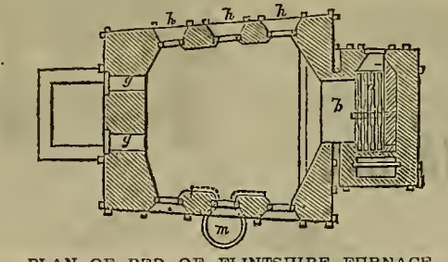
Soldering Fluxes.

Let us first consider the familiar cases of soldering fluxes. For soft soldering we may use rosin or ammonium chloride (sal ammoniac) or hydrochloric acid (spirits of salt). What happens in such cases? The tin-man, for example, places a stick of solder and alloy of tin and lead on his work and applies the soldering iron. If no flux is used the solder melted off from the stick forms a little ball which stands sluggishly on the tin plate and is ineffectual. If, on the other hand, a little powdered rosin is there when the soldering iron is applied the melted solder "runs," spreads itself with decided fluidity over the surface to which the rosin has been applied. The solder flows, and hence the rosin is fairly regarded as a flux.



LONGITUDINAL SECTION OF FLINTSHIRE FURNACE.

Take another case. Two pieces of brass, fitted or pressed together with considerable surface of contact, are to be united by soldering. If these are placed in the fire, bound together, and heated to no matter what temperature, and a piece of soft solder be applied at the boundaries of the surfaces in contact no solder will run between these surfaces. If, however, a solution of sal ammoniac, or hydrochloric acid, or chloride of zinc, be dropped or brushed against the edges of the joints just when the metal is about the heat of boiling water, and this liquid be thus made to run into the joints, a great difference is made. The workman now has only to carefully heat the metal to a certain temperature (presently to be defined) when he finds that on application of the stick of solder it not only melts, but spreads or runs rapidly over the surface that was moistened by the flux; and if the operation is skillfully performed it insinuates itself with the fluidity of water between the joints, however close fitting they may be. The fluidity thus imparted is even more decided than in the first case.



PLAN OF BED OF FLINTSHIRE FURNACE.

Hard Soldering.

Whether silver soldering or brazing, is performed in a similar manner, excepting that the silver or the "spelter" (a fusible brass) is applied in granules mixed with the flux in a state of powder, the flux in these cases being borax.

The writer has had considerable experience in both hard and soft soldering of brass work, and after some reflection has framed the following theory:

He is quite satisfied that these fluxes have no effect on the melting point of the solder, nor even any direct effect on its fluidity when melted, and believes that their whole efficiency depends on their power of presenting to the melted solder a pure metallic surface, to which it can adhere, or in fact alloy itself more or less completely. We know that melted tin, or lead, or zinc will thus adhere and alloy themselves to clean surfaces of other metals, just as mercury will amalgamate with certain metals. If a piece of dirty brass or copper be dipped into a bath of tin or lead, or the solder alloy of these, it will come out unaltered; but if it be very carefully cleaned it will be "tinned" all over by them. The tinning and galvanizing of iron plate further illustrates this.

How do Fluxes Act?

How, then, do the above-named fluxes act? Let us consider the rosin first. This is a hydrocarbon, a powerful reducing agent, and which, when heated, combines with the oxygen of such metallic oxides as those of tin, and thus effects a reduction of the pure metal on the surface to which it is applied. Thus the tinman deoxidizes his tin-plate surface, and then his solder amalgamates or alloys itself freely with and runs over or "wets" it. We take the liberty of using this term "wets" on account of its analogy with the familiar action of water which adheres to some surfaces or wets them, but runs off of others, such as greasy or dusty surfaces. This difference corresponds to the action of the solder with and without the flux.

But what is the action of the ammonium chloride? Careful observation enables us to answer this question. After applying the solution, the water dissolving the salt boils off, and there is left behind a white coating of the salt itself. Then we go on applying more heat, and if we are skillful, we watch this white fruit, and when we see it begins to dissipate by volatilizing in white fumes, we apply the solder before the last of it has gone. Then the solder runs, but if we had applied it sooner or later we should have failed.

In this case we believe that the ammoniacal salt dissolves the tin film of oxide, forms a compound which, like all the other compounds of ammonia, is volatile at a certain temperature. Now in this case the temperature of volatilization of the flux corresponds to the melting point of the solder, and hence their adaptation to each other.

As our practical readers know, especially the old hands, the use of sal ammoniac is now rather old-fashioned, having been nearly superseded by solutions of zinc in hydrochloric acid, or of the acid itself.

The action of these is the same as above described, but more decided and demonstrable, just as they are more efficacious. The hydrochloric acid dissolves the oxide, and the chloride thus formed is a volatile salt, especially the chloride of zinc.

In our apprentice days, when we received our first lesson in soldering together the segments of a "staff head" before turning it in the lathe, we were told to watch the brass until it became "beefy," and then apply the solder. What was this beefyness? We have tested this question experimentally, and find that it is due to a removal of a superficial film of zinc from the brass, thus exposing a red or coppery surface, to which the term "beefy" may be fairly applied when it is hot and free from oxide. The zinc in the brass oxidizes more readily than the copper, the zinc oxide is more readily soluble in hydrochloric acid or chlorides, and zinc oxide and its salts are more volatile than those of copper. Hence the preferential removal of the zinc and exposure of the beefy copper.

The same beefyness is displayed in hard soldering, and may be seen even after the soldering is completed and the work has cooled if some portion of the brass surface that was denuded by the flux was not covered by the brass solder. Brass tubes frequently show this.

But Why is Borax Used

Rather than chlorides, and how does it act? To answer this question we must consider the chemical properties of borax. It is a compound of boracic acid and soda, nearly resembling water glass, which is a compound of silicic acid and soda. Both of these when heated with metalic oxides form glassy compounds. Blowpipe analysis largely consists of fusing metalic oxides with borax or boracic acid, thus obtaining a glass bead in which the oxide is dissolved, the color and other appearances of such bead indicating the presence of the particular oxide. When powdered borax is laid over the metal to be soldered, and the metal is heated, the borax fuses, forms a glassy film upon the surface of the metal, which film takes up all the oxide and combines with it, forming a glassy borate of the metal. But this is not sufficient, for if that glassy film remained it would be as bad as the oxide in preventing the adhesion or amalgamation of the solder. Here then comes to our aid another property of the borates, viz, their volatility at high temperatures. The borax, with the oxide it has taken up flies off at a bright red heat, just at the temperature at which the granules of silver or the spelter brass melt. Thus they fuse upon a virgin surface of clean metal and unite with it.

We have thus gone a little aside from our direct subject on account of the confusion that the use of this term "flux" may induce. Borax is also used as a flux in metallurgical operations where a metal, such as gold, mixed with impurities is melted. These impurities are taken up by the borax, made into a fusible glass, and thus fluxed or melted away. It is not the gold which is made more fluid, but the oxides of the baser metals that have to be removed.

The Fluxing in the Blast-Furnace

Is similar to this. Its action is not the liquefaction of the iron itself, but the gathering together of the impurities of the ore, converting them into a glass that shall fuse and run down with the melted metal, for we must always remember that the fundamental problem of the modern blast-furnace is that everything pitched into its throat must come out either as a gas or as a liquid. The retention or formation of any infusible solid would choke or "gob" the furnace and put an end to its profitable operation.

Silicic and boracic acid are the two chief glass-making agents, the boracic glasses fusing at lower temperatures than the corresponding silicic glasses, and also being more volatile. But we may now dismiss these, and confine our attention to the silicates, and they do the fluxing in the blast-furnace.

This statement may appear paradoxical for the moment, seeing that not silica, but lime is the so called flux of the blast-furnace charge. This is easily explained by reference to the analysis of the clay ironstone ores already given. They all contain silica; in some cases partly free as sandy matter, or combined with alumina, or combined with the iron itself.

Silicate of alumina alone is objectionable, on account of its high fusing point. Silicate of iron fuses readily enough, but is a thief, as it carries away as useless glass the material we are seeking to obtain as reguline metal. We therefore require to add something that is more powerfully basic than the iron or its oxides, which will therefore combine more readily with the silica, and this should form a glass that is readily fusible and which will somehow separate itself from the melted iron. Cheapness is another primary desideratum.

All of these desiderata are united in lime. It is a powerful base, it is very abundant and cheap; its glass is much more fusible than iron, and is also so much lighter that it floats freely on the top of the melted iron, and thus may be run off through an overflow conduit or tap hole. Lime, therefore, is used, but it must not be used at random for the following reasons:

If the supply of lime is not sufficient to combine with the silica, this will unite with the oxide of iron and form a wasteful iron glass, or its silicon will remain excessively in combination with the iron itself. If, on the other hand, the lime is in excess, we may get into trouble, due to the fact that uncombined lime is a most refractory substance, practically infusible, as proved by its use in the lime light where a mixture of oxygen and hydrogen gases in vivid combustion strikes against a cylinder of lime, making it so intensely white hot that the light it emits is the most brilliant obtainable. This oxyhydrogen is hotter than any furnace yet constructed.

Cinder or Slag.

This explanation of the rationale of fluxing in the blast furnace also explains the composition of the cinder (so often misnamed "slag," as we shall explain hereafter), which carries away everything excepting the pig-iron and the gases. It is mainly a lime glass, and, being a glass, a multitude of schemes have been devised and patented for using it as a material for bottles and for other purposes to which glass is applied. The inventors have not sufficiently considered the fact that lime glass is much more friable than lead glass, or soda glass, or potash glass, or the mixtures of these that form the material for our windows, bottles, etc.

The problem of utilizing this mixture of silicates in which silicate of lime variably preponderates is not yet solved, on a scale commensurate with the supply of the material. It still remains a worse than worthless waste product, as its disposal is costly, partly on account of its bulk and weight in carriage, and partly on account of the ground it covers and renders useless. Of all the waste products of British manufactures this one is about the most unmanageable.

The connection between the two drifts in the Sierra Nevada mine was perfect. The drill hole that was run from the center of the face of one drift came out exactly in the center of the other. Thus there will be no difference of levels to adjust. In the south drift—much the longer of the two—there is already a serviceable temporary train, which can with little work be enlarged to the size required for a permanent one. As the level has been pretty thoroughly drained out during the progress of the drifts, there is nothing to fear from water in crosscutting, and the ventilation will be good at all points.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles-Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

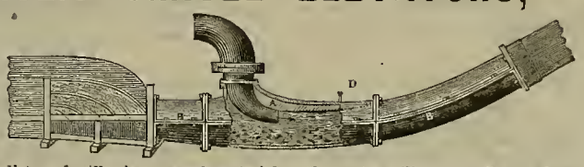
Sporting, Cannon, Mining, Blasting and HERCULES Powder.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - - - San Francisco, Cal.

HYDRAULIC GRAVEL ELEVATORS,



For working flat gravel mines that have no dump.

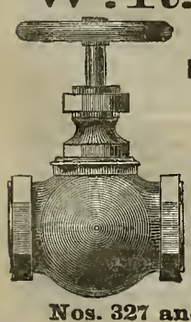
Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY.

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

W. R. ALLEN & CO.,



IMPORTERS OF

Iron Pipe and Fittings,

Lift and Force Pumps,

Brass Cocks and Valves,

For Steam, Water and Gas,

Sheet Zinc, Iron Sinks,

Plumbers' Goods.

Nos. 327 and 329 Market Street, Cor. Fremont, S. F.

Colorado Iron Works,

MANUFACTURERS OF

ENGINES, BOILERS, RAILWAY CAST AND WROUGHT WORK, BRIDGE WORK, BOLTS AND BOLT ENDS, BUILDING WORK, ETC.

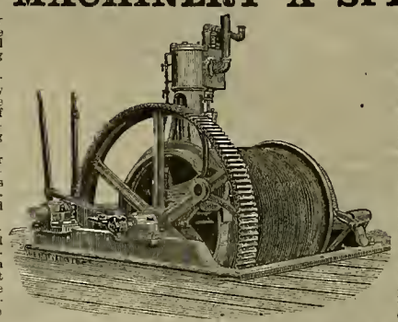
MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the



following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupellation Furnaces, Market Kettles, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

COLORADO IRON WORKS,

P. O. Box, 1921, - - - - Denver, Colorado.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Cold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description.

WAREROOMS: 92 & 94 Liberty St., New York,

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of **Morey & Sperry** are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of **Morey & Sperry**, will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-Class.

MOREY & SPERRY MINING MACHINE CO.

The best of

Through Dewey & Co.'s Scientific Press Patent Agency.

No. 252 Market Street. Elevator, 12 Front St., S. F. Telephone No 658

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

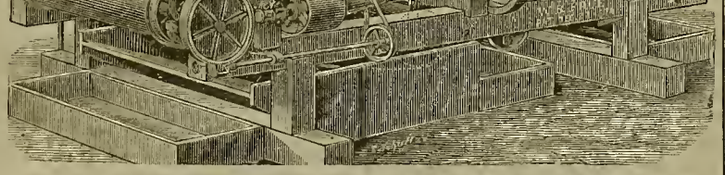
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES,

SAVE YOUR GOLD!

— BY USING —

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save more gold than any other method, and double the amount of the same surface of ordinary copper plates. The only plates that have proved durable and satisfactory.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

San Francisco Gold, Silver and Nickel Plating Works,
653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

Send for Circular. EDWARD G. DENNISTON, PROPRIETOR.

Awarded the First Premium at every Fair of the Mechanics' Institute for the last 12 Years.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

ADJUSTABLE PISTON-PACKING.—Louis Herbert, Hicksville, Cal. No. 266,365. October 24, 1882. This invention relates to an improvement in the regulation and adjustment of piston-packing; and it consists of a conical nut which fits upon a screw-thread upon the piston-rod, so that by turning the rod the cone will be advanced within the piston. The piston may be composed of a head and a follower, between which are a number of metal sections surrounding the piston-rod. The exterior surface of these sections, when all are in place, form a cylindrical body between the head and the follower, upon which the elastic packing is fitted. The interior of this sectional cylinder is bored conically to allow the nut, before mentioned, to fit within it. When the nut is advanced within this conical bore it will separate the sections, forcing them outwardly, and will thus expand the packing equally in every direction. In combination with this mechanism are employed a pawl and ratchet to hold the cone wherever desired and prevent its turning back, so as to relax the packing.

HAME-TUG CLIP.—Nathaniel D. Fowler, Marysville, Cal. No. 266,357. October 24, 1882. This invention relates to improvements in harness, and more especially to a clip or hox for the hame-tugs, the object of which is to secure the tuge to the harness. It consists in the provision of a peculiar metal hox or clip, made preferably of malleable iron, said hox being fitted upon the hame-loop at one end and adapted to receive the end of the leather tug in the other, wherein said tug is riveted.

New Treatment of Tailings.

Mr. Huntley, the assayer of the Girard mill, is engaged in a very interesting experiment at present. He has entered into negotiations with the Way Up company, and is endeavoring to save the tailings of the mill run recently made at the Girard. The tailings have been caught up in an artificial dam, and from there conveyed through a series of sluice boxes and settling vats by means of water. In each of the boxes and vats is deposited some chemicals, which succeed in retaining the bullion while the dirt escapes. The experiment is pronounced successful, and is highly interesting to mining men, as considerable bullion can be saved by the operation at very little expense either in labor, trouble or money.—*Tombstone Republican.*

Mr. Huntley, who is referred to in the above item, is personally known to the editors and publishers of the PRESS and they are glad to see he is having an opportunity of bringing his practical talents to the front. Mr. Huntley is a graduate of the University of California, and passed some time in the assay office of Mr. H. G. Hanks, now State Mineralogist. Mr. Huntley is a young man of a high order of intelligence and educational training, and the educational training he has had has fitted him exceptionally well for the position he fills. It is a pleasure to note the success of so worthy a young man. With more people of his character in positions of responsibility the mining interests would be greatly benefitted.

RICH SLAG.—The Eureka *Sentinel* says: A month or so ago the Richmond Company bought the old Hoosac slag pile from J. S. Capron for $6,000. The company has been hauling the slag away ever since, and reducing it at its works. We understand that over $40,000 have been obtained from these workings already, and the slag pile is scarcely scratched. It seems that in the earlier days of smelting here, when the Hoosac works were running on custom ore, that much of the precious metal was lost. It is being recovered now very handsomely.

THE value of the lead ore produced in the State of Kansas for the year ending with August, 1882, is reported at $1,260,000.

THE miners of the Tyersdale coal region in Maryland have struck for an advance in wages.

OUR Wood river exchanges report bad weather in that locality, and provisions scarce.

ANTIMONY is selling in Liverpool at £44 to £46 per ton for French Star regulus.

Thanksgiving.

A Proclamation by the President of the United States.

In conformity with custom, the annual observance of which is justly held in honor by this people, I, Chester A. Arthur, President of the United States, do hereby set apart Thursday, the 30th day of November next, as a day of public Thanksgiving—for the blessings demanding our gratitude are numerous and varied—for the peace and amity which subsist between this Republic and all the nations of the world; for freedom from internal discord and violence; for the increasing friendship between the different sections of the land; for Liberty, Justice and Constitutional Government; for the devotion of the people to our free institutions, and their cheerful obedience to mild laws; for the constantly increasing strength of the Republic while extending its privileges to their fellowmen who come to us; for improved means of internal communication, and increased facilities of intercourse with other nations; for the general prevailing health of the year; for the prosperity of all our industries; for the liberal return for the mechanic's toil; for affording a market for the abundant harvests of the husbandmen; for the preservation of the national faith and credit; for a wise and generous provision to effect the intellectual and moral education of our youth; for the influence upon conscience of a restraining and transforming religion, and for the joys of home. For these and many other blessings we should give thanks.

Wherefore, I do recommend that the day above designated be observed throughout the country as a day of national thanksgiving and prayer, and that the people, ceasing from their daily labor, and meeting in accordance with their several forms of worship, draw near to the throne of Almighty God, and offer to Him praise and gratitude for the manifold good which He has vouchsafed to us, and praying that His blessings and mercies may continue.

And I do further recommend that the day thus appointed may be made a special occasion for the deeds of kindness and charity to the suffering and needy, so that all that dwell within the land may rejoice and be glad in this season of national thanksgiving.

In witness whereof I have hereunto set my hand and caused the seal of the United States to be affixed. Done at the City of Washington this 25th day of October, in the year of our Lord, 1882, and the 107th of the Independence of the United States.

CHESTER A. ARTHUR.

By the President. FRED'K. T. FRELINGHUYSEN,
Secretary of State.

THE COMING TRANSIT OF VENUS.—There will be about 300 points of observation of the transit, which occurs on the 6th of December of this year. The United States Government has appropriated about three-quarters of a million of dollars for its part of the work. Professor DAVIDSON, of this city, will be stationed, by his own choice, at Fort Seldon, a point 50 miles north of El Paso, on the Rio Grande.

BILL NYE is of the belief that mining stocks, if properly irrigated, are productive of wonderful results.

Extra Type for Sale.

We offer Scotch brevier type (same as used on this paper) for sale in any quantity from 100 lbs. to 1,000 lbs. for 25 cents per lb., if ordered soon. Also, several hundred pounds of nonpareil at favorable rates. The type is in good condition and is of a very durable character.

DEWEY & CO.

The Best Hotel.

The best hotel in Stockton is the Yosemite. Mr. James Cavin, the proprietor, has long maintained the leading house in that city. On all extra occasions the Yosemite is made headquarters, as on the occasion of the late Farmers' Convention.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter.*

To Engineers and Draftsmen.

WANTED.—A good wood engraver. Also, a draftsman, who can make pen and ink drawing on paper or stone. Apply at this office.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired), he sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

REMITTANCES to this office should be made by postal order or registered letter, when practicable; cost of postal order, for $15 or less, 10 cts.; for registered letter, in addition to regular postage (at 3 cts. per half-ounce), 10 cts

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their agency from week to week and year to year.

Old Papers Wanted.

Twenty cents each will be paid for a limited number of copies of any of the following Nos. of the MINING AND SCIENTIFIC PRESS, if received soon at this office: No. 1, of Vol. 13, 1866; No. 5, Vol. 18, 1869; Nos. 1 and 26, of Vol. 20, 1870; No. 1, of Vol. 22, 1871. Also, 10 cents per copy for Nos. 2, 3, 4, 7, 10, 11, 12, 13 and 15, of Vol. 30, 1875. If any one who has files of back volumes of the PRESS, which they may like to dispose of at a moderate rate, will send us a memorandum of the same and the price, we may be able, sooner or later, to assist in their disposal.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

Mining and Other Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Land Purchasers' Association.—Location of principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors or Trustees, held on the 3d day of October, 1882, an assessment of Four Dollars ($4.00) per share (being a part of the 44th instalment on the subscription to the stock) was levied upon the capital stock of this corporation, payable immediately to the Secretary at 318 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on MONDAY, the Thirteenth (13th) day of November, 1882, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on WEDNESDAY, the THIRTEENTH (13th) day of DECEMBER, 1882, to pay the delinquent assessments, together with the cost of advertising and expenses of sale.

C. S. WRIGHT, Sec'y.

OFFICE—318 Montgomery street, San Francisco, California.

N. B.—This assessment is to pay the taxes on the property of the Association for the current year.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates rehlasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to wate. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

THE CONSUMERS' COMPANY.

VULCAN B B,

The Best Low Grade Explosive in the market. Superior to Black or Judson Powder

VULCAN NOS. 1, 2 AND 3,

The best Nitro-Glycerine Powders manufactured. Having secured large lots of the best imported Glycerine at low prices, we are prepared to offer the mining public the very strongest, most uniform and best Nitro-Glycerine Powder at the very Lowest Rates.

SPECIAL INDUCEMENTS IN PRICES.

Vulcan B B Powder (in Kegs or Cases) is Unequaled

For Bank Blasting and Railroad Work.

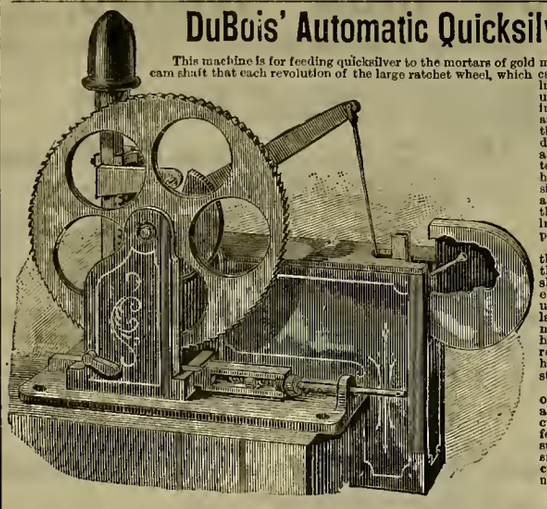
Caps and Fuse of all Grades at Bottom Rates.

The Central and Southern Pacific Railroads Use Vulcan Powder and no Other.

Vulcan Powder Co., 218 California St., S. F.

S. HEYDENFELT, - - President.
H. SHAINWALD, - - - Secretary.

DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.

The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.

A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.

Price, complete, $75.

For Sale by **WHITNEY & MARSHALL,** Sole Agents

22 & 24 Fremont St., San Francisco.

Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

Contains no Nitro-Glycerine or Chlorate of Potash, and is the only High Explosive Manufactured in America that does not contain these Dangerous Ingredients.

In Use for Seven Years Without a Single Accident.

TONITE POWDER CO.,

No. 310 California Street. - - - SAN FRANCISCO.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, NOVEMBER 11, 1882.

VOLUME XLV Number 20

Mew Mexican Mines.

Recent Discoveries in the Black Range.

(Written for the PRESS by GEORGE MADERIA.)

Leaving the oars at the A. T. & S. F. R. R., at Nntt Station, we take stage for Lske Valley, distant 15 miles. Nutt is rapidly improving nnder the impetns of the new strikes, and the inrnsh of "tenderfeet." Arriving at the Sierra Grande mines, we presented our credentials to the snperintendent, M. A. Gillette, formerly of California. He placed us in charge of the foreman, Wm. Skyrme, whoguided ns through the wnnderful mine. The ore commences on the s'ope of the limestone hill, in the grass-roots, and pitches at the same angle (abont 15°) nnder a lime capping, until it reaches a depth of 60 feet or more—the end of the present workings. The ore deposit varies in depth from one or two feet to 12 or more, until it reaches what is known as the "Bridal Chamber," where the exhibit of rich ores is really astonishing. The ore body in this chamber is 40 feet in depth and of unknown width, as it has not heen followed to the east, west or south for any great distance. On the floor of the second gallery lies

A Mass of Horn Silver

Called the "Jackson Baby." This mass of ore is nearly six feet long, four wide and two thick, and estimated to contain from $60,000, to $80,000. The lnmp which astonished the Denverites at the late exposition was from this chamber. We saw in the ore house one lump containing $6,000, and ore in sacks of the same kind to the extent of $100,000, some of which is almost pure silver. The ore assays 90%. Nor is this all we saw in the retorting rooms—$210,000 in silver bricks, the product of the last month's run. We were satisfied after looking through the mine that this could have heen douhled or trehled. A mass of this ore weighing 240 lbs. was melted in the pots and a brick 990 fine, weighing 1,903½ ozs. obtained, leaving 187 ounces in the slag, making a total of $2,400 or ahout $10 per pound.

The "Jackson Baby" will weigh over four tons. This mass was connected with another mass, which still remains in place, and has not heen excavated. On every side are rich carhonates and chlorides, and what may he contained in the deposit cannot he estimated, as its extent is not known, no levels having heen run south. Some 65 tons per day are taken from the mine. There are large quantities of ore of lower grade on the dump, say, 3000 tons, which will work from $30 to $100 per ton. Such ie a hrief descriptlon of thie wonderful deposit.

The mill ie a first-olase one, the machinery having been made by Prescott, Scott & Co., of San Francisco. Water is forced from the lake, four miles distant.

Lake Valley,

The new town, is composed of hastily hnilt honses of wood, adohe and oanvas. It mnst have at least 500 or 600 inhabitants. Some half dozen hacks and eteges run to Nntt station, hringing in each morning their loads of passengers, and returning in the evening with as many as they hrought in, like ants going and returning to the hill they move.

There are other mines in this section, hut none of note. Water is ecarce in this vicinity, none hut what is furnished hy the railroad at Nutt, nor can any he found hy sinking. Lake Valley city is supplied by water wagons.

Taking a horse, we flanked

The Black Range

For a distance over the trail of 19 miles over rolling hills and mesas, orossing several small streams whose hanks were lined with etunted oak, ash and walnut trees. The amole, with its spreading, palm-like heads decked with a long stalk 10 or 15 ft. long, looking like a hnge plnme waved in the wind. Wild turkey and deer are ahundant in these mountains, whioh are more or lese wooded. Caotus of many varieties etudded the rocky bluffs or grew along the wayside, some with hright ecarlet fruit. At dusk we reached Kingston, in the heart of the range, pioketed our horse, ohewed our hacon, and bedded in a canvas lodging-house with good heds. An enterprising Californian had heen an early arrival, hringing a complete establishmeut with him, and is doing a land-office husinoss.

Kingston is 6,000 ft. above the sea, contains 20 or 30 canvas and wooden honses, two stores and a number of saloons.

The early morn found us climhing the steep mountain for a mile and one-half, when we arrived at the Bullion. This ie by fer the finest hody of ore yet etruck in the vioinity. The ore is the hlack sulphurets of silver, and looks much like the Comstock ores.

It assays from $1,000 to $2,000 per ton. There is on the dump sacked and otherwise ahout 50 tons. A road has been huilt to connect with the Kingston road, and the ore will move ere this is in print.

The strike is on a limestone point, and is what is known as a pipe or chimney. All the ore has heen taken out from the surfaoe down to a depth of 75 ft. The shaft is ahout four feet square at the eurfaoe, hut expands at eome points on the way down to 10 ft. The oountry rock ie lime, but at the hottom numerous stringere of ore are coming in, and the chancee are that a large body of rich ore will he found when the oontsct with the porphyry is made, which is on the surface about 75 ft. from the shaft. Twenty-fonr tons of this ore from above the first 18 ft. was worked at the Lake Valley mill, and returned $10,400. The ore has increased in richness as it descended. The mine is owned hy J. E. Wurtzhach, D. H Jackson, J. W. Southwick, Col. James C. Logan, of California, E. D. Town, and F. M. Chapman, who is superintendent at the mine.

Joining the Bullion on the north and hut 80 ft. from the Bullion shaft is the south line of the Superior, owned hy Gov. Geo. C Perkins, Col. James E. Logan, Capt. Thomas Burns, the present superintendent, and others. Ore has heen fonnd all over the Superior grounds, at one point on the extreme north a lode, three and a half feet wide, has heen discovered. The south shaft is down 70 feet with some ore. This will be sunk to a depth of 100 ft., and crosscnts run to the porphyry on the west 50 ft. distant, and also into the line to the east.

A fine prospect of ore has heen found 500 ft. from the above shaft. There is a large deposit of iron ore, which carries silver, hut no work has yet been done on it for lack of time. The lime and porphyry contact continues along the entire line of the Superior, also along the line of the Polar Star, the north extension of the Superior, which has heen purchased hy the same parties. The indications are that the hody of ore in the Bullion rnns through the grounds of the Superior Co.

We have some ore knocked from the croppings ahove the grass roots which show native silver.

One mile west of the above mines is the Iron King, a large deposit of

Low Grade Argentiferous Iron Ore,

Which will he very valuahle for smelting or flnxing. There has heen much work done on this mine, and a shaft is now heing sunk to penetrate the deposit. The country rock is lime and porphyry with quartzite dikes.

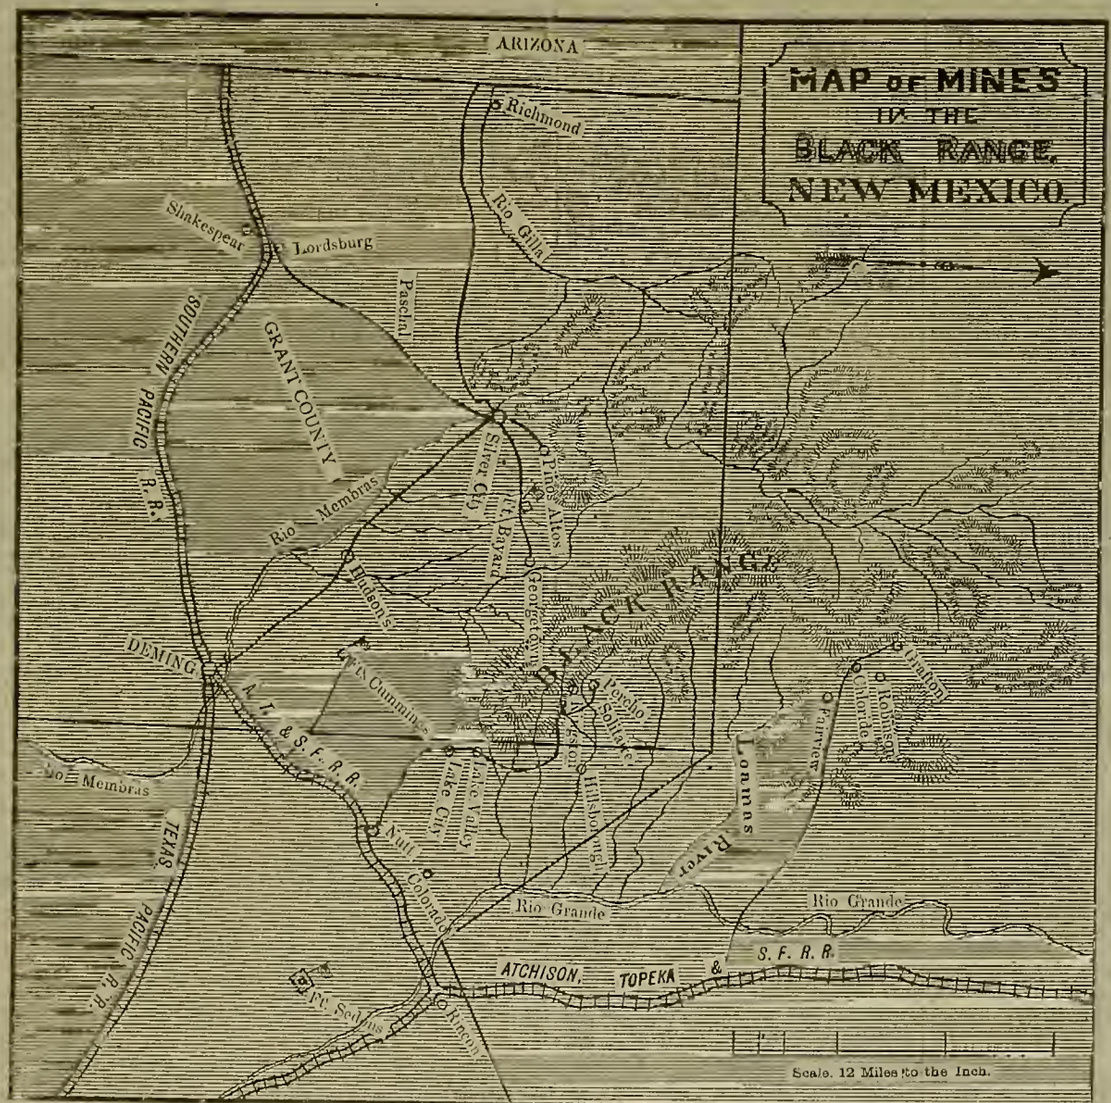
A shaft of 70 ft. fails to penetrate the iron ore to the hottom. Ore from the hottom went $30 to the ton. We are nnacqnainted with the owners. Wm. Welch is snperintendent at the mine.

Four miles from the Superior, over two ridges, we reach the St. Clair or Solitaire mine, recently honded hy Governor Tahor, of Colorado. This is the point where the

Rich Float Ore,

Both native and chloride, has heen found. It is looated on a hranoh of the North Perche, on the right hank, on a limestone ridge, which oomes down from the north. It is hut a few hundred feet in width, and hounded on either hand by porphyry. The float ie found on the

(CONTINUED ON PAGE 316.)



CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

A Visit to the Sweetwater Mines.

EDITOR PRESS:—As an old subscriber, I take the liberty of writing to you about what I saw in this promising new mining camp. On the 19th inst. a friend of mine and myself left Bodie for Clinton. Arriving there, we proceeded to the Summers mine, a distance of about three miles, in a westerly direction, up a steep mountain, where we fell in with Dr. Summers, one of the proprietors, as well as superintendent, of the mine. He showed us through the mine, and it looked excellent. The ledge cut by the lower tunnel, at a depth of 300 ft., is about 30 ft. wide from wall to wall, and runs north and south, with a westerly pitch. The pay streak, which is next the wall, is about 6 ft. wide, of a rich black sulphuret ore, carrying horn silver, and averages over $100 per ton. They are running a five-stamp mill on this mine, which crushes about six tons per day.

On a due line north of this mine, about half a mile, is situated the Homestake, owned by Pat Fahey & Co., of Bodie. This is a very fine prospect, and promises some day to richly reward the owners. We found two men engaged in running a tunnel in this mine, and they had taken out a lot of very rich-looking rock, of the same character as that at the Summers mine.

Running parallel with and west of the Homestake is the Silverado, the best prospect for a big mine I have seen in the district. As yet they are down only a distance of a little more than 40 ft., and and at the time of our visit had cut into the ledge from the bottom of the shaft a distance of 15 ft., all quartz, and some of it very rich. This mine is owned by Pat Fahey, Tom Hill and others, of Bodie. It is very rich in horn silver, and is a very good milling proposition. There are also other good properties, such as the Great Western, California Comstock, Lookout, and others, that show some very good ore. From the present showing, I predict a bright future for the Sweetwater mines. P. F.

Bodie, Cal., Oct. 28, 1882.

The Two Plans.

Mining for Gold and Mining for a Mine.

Meeting an old Silver City acquaintance a day or two ago, we said: "How does it happen that you Silverites now manage to get good pay out of so many of the mines about your town, when some years ago you were taking out nothing at all?"

"Well," said our friend, "I will tell you. We are now mining for pay—for silver and gold—whereas, formerly, we were merely mining to make mines. Then when we located upon a quartz vein we went to the foot of the hill or to the bottom of the deepest ravine in the vicinity and started a big tunnel. This tunnel looked well, taken in connection with the location, but it was generally so far away that it never reached the vein for which it was started. The same way where there was no chance for a tunnel. We started a shaft. Making our calculations from the dip of the vein, we went off such a great distance, in order to come in deep, that we never got down to pay. The fact is, we had others more in mind than ourselves. We were fixing up things in shape to catch the eye of the capitalist. We were mining to make a mine that we thought would capture some man with plenty of money."

"And you didn't catch your capitalist?"

"O, yes, we did in a good many instances, but in nine times out of ten he went on with the tunnel or the shaft till he got sick of it, and gave it up without being able to tell where his vein had gone."

"You all wanted a big thing or nothing!"

"Yes, that was about it. The capitalist was also mining more for the purpose of making a mine than to take out silver and gold. He was preparing to capture a bigger capitalist than himself."

"So you all ignored the pay that was in your vein at the top of the ground?"

"Went as far away from it as we could get, I tell you. Just as soon as we became satisfied that there was pay in our vein we struck out to a point half a mile distant and prepared to strike it 1,000 feet deep. Finally, when no more men came to buy mines and when we had waited for capitalists until about starved out, we quit mining to make mines and went to mining to make a little money. Then the mines smiled their golden smiles in our faces and rewarded our honest toil. We left the long tunnels and the deep shafts to take care of themselves and went for the gold wherever we could find it. We gave up all the fine, showy, square work that was to catch the eye of the moneyed man, and followed out any and every streak of quartz that contained pay. We quit pretty mining and went for pay. And that is what we are still doing. When we find gold we dig it out at once; don't shoulder our picks and run off to start in half a mile away."

It is probable that in not a few places on the Pacific coast there are still many men who are mining more for mines than for either gold or silver.—*Virginia Enterprise.*

Flameless Substitute For Powder in Blasting.

At a recent session of the Coal Mining Department of the Yorkshire College, at Leeds, a lecture was delivered on "Coal Getting by the Lime Process and Other Flameless Substitutes for Gunpowder," by Mr. Arnold Lupton.

"The danger of using gunpowder in mines had," Mr. Lupton remarked, long been recognized, and it was a rule never to use it in any mine or any part of a mine, unless it had been found by examination to be free from inflammable gas in such proportions that it could be detected with a safety lamp; and in mines liable to sudden eruptions the use of gunpowder was often prohibited altogether. Twenty years ago it was generally believed that no explosion could occur in a mine unless a there was a proportion of gas, varying from 6 to 20% of the mixture of air and gas; this had now been found to be a mistake, for it had been found out that a violent explosion could take place if only there were two or three per cent. of gas present, if in addition to the gas there was a great deal of dust in the air. All dry coal mines were dusty, and therefore liable to explode, even when reported quite clear of gas. Therefore, in fiery and dusty mines the use of gunpowder was always attended with risk. In many mines, consequently, the use of gunpowder had been either entirely prohibited, or only used when most of the men were out of the pit. In such mines it was important to find a substitute for gunpowder. In order to estimate the importance of that question it was necessary to consider what the cost of getting coal in ordinary cases was. Coal could be got and put in railway trucks for a cost varying from 3s. 6d. to 5s. 6d. a ton, and of that only 9d. was for work requiring powder. What had now to be considered was how that item of 9d. was affected by the disuse of gunpowder. At some colleries the abolition of explosives would cost 1s. 1d. per ton, and it was doubtful whether that amount would be exceeded in any colliery in the kingdom. It was very difficult to drive stone headings without explosives, but Col. Beanmont had a machine that would drive a heading in the hardest rocks met with in coal mines, except whinstone, at the rate one ft. an hour, which was very much faster than the ordinary rate at which such work could be accomplished; the machine was driven by compressed air, and the use of explosives was unnecessary.

The lecturer then explained a method of blasting with gunpowder and dynamite, in which a water cartridge was used, and the flame was entirely prevented. Mr. Macnab had given a great deal of attention to this invention. A compressed air cartridge had been used; it was a cast-iron shell, and was exploded by air at a pressure of 10,000 lbs. on the square inch. Also, Grafton Jones' hydraulic wedge, Chubb's hydraulic ram, and Macdermott and Elliott's multiple expanding wedge. Having dealt with various processes for getting the coal without the aid of explosives, Mr. Lupton said that the last method to be introduced was the lime process. It had been known for ages that quicklime had the potentiality of heat and power. When mixed with water it developed considerable heat, and expanded in volume. It was not until recently that a practical method of using quicklime for coal getting was discovered. In this process lime was applied exactly in the same way as gunpowder, only in a much larger quantity, ten pounds of lime being used in a charge when one-third of a pound of gunpowder would suffice.

Having described how the holes were drilled, Mr. Lupton said they were charged with the purest kind of lime, in the form of a cartridge four and a half inches long by two and a half inches in diameter. The pressure used was one and a half tons to the square inch, and the cartridges as soon as made were packed in an air-tight box. Seven cartridges were gently rammed into each hole, which was then stemmed with clay. When the holes were charged a hand force pump was connected in turn by a flexible tube, with small tubes projecting from each hole, and fitting into grooves moulded on the sides of the cartridges. By this means a given quantity of water was pumped into each hole, equal in bulk to the lime. A tap at each end of the tube was then closed, and in one or two minutes the chemical action of the lime and water caused a great deal of heat, which converted the remaining water into steam. The pressure of this steam caused the coal to crack. In a short time, however, the steam either escaped or condensed, still the lime continued to work and expand, and on examining the cartridges after they had broken down the coal, it was seen that they enlarged the bore-holes. About half an hour after the charge had been watered the sprags might be withdrawn, and the coal would come down. This process had been successfully tested in hundreds or thousands of cases in South Wales, Lancashire, Durham, Derbyshire, Yorkshire, Belgium, and elsewhere, and been approved by many most competent mining engineers.

Compared with Grafton Jones' hydraulic wedge, the lime process had the advantages of cheapness, safety, and economy of labor. When, however, the wedge machine was applied with good luck, it could, no doubt, be worked as cheaply as the lime process, but it sometimes happened that the machine got fixed in a hole, and some trouble was then required to extract it. One advantage of lime over gunpowder was that several cartridges could be working at one time along a considerable length of face, each helping the other, whereas in gunpowder blasting only a single shot was fired. Only an approximate estimate could be given of the cost of working the lime process. Allowing five hours for boring 15 holes, two and a half hours would have to be given for charging and watering the same number, and, in practice, the work would have to be done by an experienced collier—paid, say, 5s. a day, assisted by a lad or a lahorer, paid 2s. 6d. a day. Supposing, then, that 15 cartridges broke 1,200 cubic feet, or 40 tons of coal, the cost would be equal to 3¾d. a ton. With gunpowder the same amount of work could be done for 2 1-10d. a ton; but, on the other hand, time was lost in consequence of men having to get out of the way while a shot was fired or while the smoke cleared away, and extra deputies had often to be engaged to fire the charges, so that, taking into consideration the greater proportion of large coal, the balance of profit might be found to be on the side of the lime process. It must, however, be borne in mind that the process was not applicable where great power was required, in narrow headings and in stone. The ideal mine of the future was one free not only from gas but from dust, and in which the use of gunpowder was superseded by lime or other flameless substitutes, and certainly the progress of engineering warranted the supposition that these conditions would ere long prevail.

In seconding Mr. Sagar-Musgrave's motion for a vote of thanks to the chairman, Mr. W. G. Jackson spoke of the great value of the Coal Mining Department of the Yorkshire College to the rising generation; and the Chairman, in acknowledging the vote, said with regard to the use of lime in blasting that where there was a hard seam of coal the lime process was of very little use, because the time that had to elapse between the injection of the water and the time when the whole force of the steam had spent itself was so long that it became a very serious factor to the calculations when compared with the ordinary process of gunpowder. Where there was a tender seam of coal and a fiery mine, so that time was not the element to be considered, but where safety was of the first importance, then he could imagine that the lime process became one of much value. In hard seams of coal, where there was not much gas, and where time was of importance, it was a different thing altogether.

Military Hill.

The Pedro Con. Mining Co., which owns the Big and Little Pedros, Idaho, Ivanhoe, Mattie Hickey and Accident, recently incorporated in San Francisco, with a full paid up stock capital, is rapidly developing its properties under the superintendency of Mr. C. G. Bilicke. On the Big and Little Pedros there are 10 outcropping veins running north and south and east and west, all of which run into the other members of this group of mines. These ore veins have been recently prospected by shafts varying in depth from 3 to 55 ft. at various points along each vein, showing that they run the whole length and width of these claims in average veins of ore two and a half feet wide, and with an assay value, on average ore, of $145 per ton. The ledge of the Green Cloud mine, which has proven a very rich one, has been prospected across the Honey Comb and the Big Pedro, showing this large ore vein contributes to the value of this group. There have been many

Rich Specimens of Ore

taken out, assaying as high as $6,000 per ton, and it is confidently believed that the ore from this mine will mill upwards of $120 per ton. There is a force of men at work upon the surface, in two shafts, taking out good ore, and in sacking the ore on the various dumps, which is to be transported to the Boston mill, near Charleston, the milling of which will soon determine the richness of these ledges. It might be a surprise to many of our citizens to learn that Mr. Geo. Rutledge has been for some time at work, with a

Night and Day Shift,

Upon a contract with this company on a tunnel commencing near the east end of the Big Pedro, which will, in all probability, he run entirely through Military hill, on this property, and which will tap all the north and south ore bodies, varying in thickness, at this depth, from 4 ft. to 10 ft. The mine is situated about two miles south from the city of Tombstone, and a good road has been completed to the mouth of the tunnel. The owners of the stock in this company think they have a mine second to none in this camp, and as there is no stock in it for sale, their affairs have been kept very quiet. The work of this company will give a new impetus to the mining industry of the immediate vicinity, which will be of great benefit to this district. Mr. John Landers, of San Francisco, is President of the company.—*Tombstone Epitaph.*

BOLIVIA COPPER MINES.—Billy Baker has gone to the Bolivia copper mines to work assessments on his mines. He has one or two mines there, which are bound to be valuable sooner or later. He worked them to a considerable extent some years ago, and one of them is considered as good a copper mine as there is in the country. There is plenty of nut pine in the vicinity of the mines, which could be utilized in reducing the ores.

Stopping Engines by Electricity.

A novel method of stopping engines, the invention of Mr. Tate, of Bradford, is at present being introduced by Messrs. Duncan Brothers, of Queen Victoria street, and appears to have given general satisfaction. The apparatus consists of an ordinary Leclanche battery, an electro-magnet, and wires leading to any position from which it may be desirable to control the engine, and buttons for completing the circuit. Also a small steam cylinder, piston, and rack and pinion gearing, which actuates the stop valve on the engine. The apparatus is constructed in a neat, compact form, and can be applied to any kind of stop valve. The electro-magnet is placed at the top and connected directly to a suspension rod which actuates a small steam cock on the cylinder of the apparatus. The circuit is an open one, and when it is desired to put the apparatus in operation, the pressure of the finger on one of the buttons, at any distance from the engine, closes the circuit and excites the electro-magnet, the effect being to release the suspension rod, which falls with a velocity due to gravity. The suspension rod in falling opens the small cock on the cylinder and admits steam, the initial pressure of steam being the same as in the steam engine cylinder. The piston in the cylinder of the apparatus immediately ascends and the rack piston rod instantly closes the engine stop valve.

The steam to work the apparatus being taken from the stop valve chamber from underneath the valve, between the valve and the steam-engine cylinder, the consequence is that as soon as the stop valve has been closed there is no longer any pressure in the small cylinder; and when it is desired to start the engine the engine driver has simply to lift up the suspension rod to its normal position and open the stop valve in the ordinary way. In lifting the suspension rod the small cylinder cock is again closed against the admission of steam, but the cock having three passages is opened for the inlet of atmospheric air. The act of opening the stop valve by the hand wheel operates also on the piston, which falls to the lower end of the small cylinder and is then reset for further use.

When applied to the stop valves of condensing engines a cock fitted on a pipe opening to the atmosphere is also actuated by the apparatus, and at the instant the stop valve is closed this cock is opened, thus admitting air into the condenser, destroying the vacuum and stopping the supply of water. The apparatus also stops the engine on which it is fitted, whenever the speed exceeds the ordinary rate by any given number of revolutions. This is effected by means of the throttle, or variable expansion valves, actuated by the engine governor. Short arms are fixed on the valve spindles, which act as fingers to press in a push, or button, at any time the valve exceeds the usual range of lift or stroke. In all cases the apparatus resets itself when the engine is started.—*London Mining Journal.*

THE MALHEUR RESERVATION.—The Canyon City *News* has this to say of the Malheur reservation: "A great many inquiries are made about the Malheur reservation; the mere fact that it has been reserved so long for the use of the Indians causes many people to think that the land is of superior quality and the climate unsurpassed. In reality there is but little land embraced within the limits of the reservation that is classed as agricultural land by the Government, and even that is situated on the north-east quarter, which is not yet available for settlement. The greater portion of the reservation consists of rolling hills, covered with good bunch grass. It is a good stock country, but nothing else at present. The elevation is such as to render the success of agricultural operations doubtful. The average hight above sea level is probably 4,000 feet. A good many persons have already taken claims; some of the settlers are from other portions of this county; some from various parts of the State, and a few from the East."

GROWING TREES TOO SLOW BUSINESS.—Artificial substitutes for the natural products of the forests have been attracting much attention for two or three years past. Our readers are already informed in regard to the manufacture of straw lumber, and now we are informed that a new company for this business has been formed at Joplin, Missouri. The *Daily News*, of that town, says: "A series of experiments were made with samples of the lumber in the presence of a number of stock-holders and others, all of which were satisfactory in the extreme. There having been expressed some curiosity as to whether the patent lumber could be worked with carpenters' tools with the same facility as any other lumber, the party all repaired to the shop of Hoyt & Chickering, where it was demonstrated that it would saw and also dress with a plane just as well as pine or walnut, and that it was susceptible to just as smooth a finish as any other lumber. It was also tested by fire, and failed to burn with the readiness of wood. Those who were somewhat doubtful about the utility of the new invention were fully reassured by these several tests, and there is no question but that straw lumber will, in a few years, to a certain extent, take the place of other kinds for inside finishing, and in the manufacture of furniture. The demand is already in excess of the facilities of the one factory, and the company organized here is confident it will have no difficulty in finding a ready sale for all that may be manufactured."

MECHANICAL PROGRESS.

About Steel.

Wm. Metcalf, a prominant engineer, in connection with Prof. J. Langley, has been studying upon steel, and from a paper read before the Engineers Society of Western Pennsylvania by him, the following conclusions are arrived at:

1. That a good soft heat is safe to use if steel be immediately and thoroughly worked, for it is a fact that good steel will endure more pounding than iron.

2. If steel be left long in the fire it will lose its steely nature and grain and partake of the nature of cast iron. Steel should never be kept hot any longer than is necessary to the work to be done.

3. Steel is entirely mercurial under the action of heat, and there must, of necessity, be an injurious internal strain created whenever two or more parts of the same piece are subjected to different temperatures.

4. It follows that when steel has been subjected to heat, not absolutely uniform over the whole mass, careful annealing should be resorted to.

5. As the change of volume, due to a degree of heat increases directly and rapidly with the quantity of carbon present, therefore high steel is more liable to dangerous internal strains than low steel, and great care should be exercised in the use of high steel.

6. Hot steel should always be put in a perfectly dry place of even temperature while cooling. A wet place in the floor might be sufficient to cause serious injury.

7. Never let anyone deceive you with the statement that his steel possesses a peculiar property which enables it to be "restored" after being "burned;" neither should you waste any money in nostrums for restoring burned steel. For "overheated" steel can be restored by first bringing it to a red heat and allowing it to cool slowly. For "burned" steel, which is oxidized steel, there is only one way of restoration, and that is through the knobbling fire of the blast furnace.

8. Be careful not to overdo the annealing process; if carried too far it does great harm, and is one of the commonest modes of destruction which the steel maker meets in his daily troubles. It is hard to induce the average worker in steel to believe that very little annealing is necessary, and that very little is really more efficacious than a great deal.

Finally, it is obvious that as steel is governed by certain and invariable laws in all of the changes mentioned, which laws are not yet as clearly defined as they should be, nor as they will be; nevertheless, the fact that there are such laws should give us confidence in the use of the material, because we may be sure of reaching reliable results by the proper observance of the laws; therefore, there is no good reason why engineers should be afraid to use steel if they manipulate it intelligently.

EFFICIENCY OF STEAM JACKETS.—At a recent trial of an engine made in Belgium on the Corliss system, the following details are given concerning the efficiency of the steam jacket: Working under average conditions, without the jacket, the engine developed 127.6 horse-power, with a consumption of 24.7 pounds of steam per indicated horse-power per hour. With precisely the same opening of the valves, and under otherwise exactly similar conditions, except that steam was admitted to the jacket, the work rose to 157.13 horse-power, and the consumption of steam fell to 19.85 pounds per indicated horse-power per hour, making in this way a gain of 19.6 per cent. A somewhat defective action of the steam traps existed the day on which these results were recorded. This trial was repeated the following day, and the consumption of steam fell to 18.96 pounds per indicated horse-power per hour, making a gain of 23½ per cent., the amount of power being sensibly the same. Comparing the mean of these two days' work, the same engine did 23.7 per cent. more work with the jackets than without, while the saving of steam per indicated horse-power per hour was 21.6 per cent. by the use of the jacket.

THE TREATMENT OF CEMENT.—At a late assembly of German manufacturers an interesting report was made by Von Froideville, in which he asserts that a really good cement, one that has been suitably mixed, not only does not crack, but even in a northern climate is able to resist the weather. If, however, too much water has been used, so that a glossy crust forms on the surface, and the whole mass is not homogeneous, the cement checks or cracks, and as soon as hair cracks appear, moisture enters and the frost destroys it. Another fault referred to in this report is that of the cement striking out, which it ought not to do. Von Froideville also says that cement can be colored nicely and permanently with suitable colors, but quite a good deal of color is necessary if it is required to entirely hide the natural color of the cement and give it the exact color desired. It is to be borne in mind, however, that the addition of any coloring substance to cement tends to give it a softer and more friable character, so that there is required a comparatively larger quantity of cement than without the color.

Industrial Progress at the South.

The rapid industrial progress of the South is exciting the wonderment of the civilized world. All kinds of industrial enterprises are being pushed to the front, and the vast natural resources of the country developed. In Tennessee, Alabama and Virginia iron and coal mining and iron manufacturing are the industries which are most flourishing; in Georgia, gold-mining and cotton manufacturing; in Florida, lumber manufacturing, orange growing and gardening; in North Carolina, Mississippi and South Carolina, cotton manufacturing and diversified agriculture, and in Texas, diversified agriculture and sheep raising. In the States of Louisiana and Mississippi silk culture is receiving considerable attention. Cotton growing is, of course, common to the whole South, and therefore no reference is here had to that industry. The extraordinarily large grain crops of the present year will insure the continuance of the work of improvement for a considerable time at least. The outlook for the South was never more promising than it is to-day.

In the matter of iron industry, it has been rather less than 15 years since the first coke furnace was blown in at the South. Its capacity running full was 9,000 tons a year. At the close of the current fiscal year there will be shown a product of 400,000 tons of coke and a fourth as much charcoal, while the real development of the iron industry at the South has only begun. The estimate for the next census year is already made at from 1,000,000 to 1,200,000 tons. All of this product finds ready market in the North, while the amount demanded for direct home consumption is steadily increasing. Mills of all kinds are being established as fast as capital finds suitable opportunities, and the growth of these industries is coincidental with the increase of crude metal production. The Southern irons are uniformly of good quality and work well. They are sought after at nearly all points where freight charges are not too high to allow transportation, and the supply of this year if it were just doubled could be easily disposed of.

AN ANCIENT GAS ENGINE.—The *Scientific American* of October 7th contains the following concerning a gas engine which was illustrated and described in one of its numbers about 36 years ago: In looking over an early volume of the *Scientific American*, we find in the issue of July 23, 1846, the following description of a gas engine which had just been invented, and which the article says, might have been seen at the store of Samuel Perry, on Front street, near Whitehall, in this city. This was probably one of the earliest gas motors constructed: "The machinery consists in part of a cylinder, piston, pitman, flywheel, and governor—in this respect similar to an engine. A small quantity of spirits of turpentine is kept in a warm state, and the vapor arising therefrom is mixed with 50 times its volume of atmospheric air. A small quantity of this hydrogenated air is drawn into the cylinder and ignited by a movement of the machinery, producing a slight explosion, whereby the remaining air—at least nine-tenths of the whole—becomes so heated that it drives forward the piston with great force. This engine is said to be capable of working 10 horse powers, and it is intended to substitute rosin instead of turpentine, which will reduce the expense of feeding it to about 50 cents per day. The ingenious inventor has had some difficulties to encounter in the construction of the first engine, but has a fair prospect of being well remunerated for his labors.

PHOTOGRAPHING AN EXPLOSION.—The United States Engineers recently photographed the explosion of a wreck, which was blown to pieces by submarine charges of dynamite, to ascertain, among other things, how long the spectacle really lasted. The result was exceedingly interesting. There were six cameras employed, and the instant of the explosion, as also the several instants when the exposures were made by shutter, were electrically timed by a chronograph. A photograph taken one-tenth of a second after the explosion showed the vessel broken, and a column of water 70 feet high; a photograph secured 1:5 seconds after the explosion showed a column of water 160 feet high; a third photograph, taken 2:3 seconds after, showed the column at its full height of 180 feet, while fragments of wreckage were in the air, but none had fallen to disturb the surface of the water; a fourth picture, taken 3:3 seconds after, showed the column falling, and the surface of the water disturbed; while a fifth photograph, secured 4:3 seconds after, showed that all was over.

LOCOMOTIVE PULLING.—A correspondent of the *Scientific American* asks, Can a locomotive pull more than its own weight? Example: If a ton engine had 70 tons of solid matter on one cart attached to it, could it draw it? If so, could it pull it more easily than if it were put into seven cars of 10 tons each, the engine not to use any substance to assist it, the track to be straight and level? That paper replies: Yes, the friction and resistance of air, etc. are less to one car than to a larger number. The pull of a locomotive is not the dead weight of the load, but merely the resistance due to friction, resistance of air, etc.

.THE Washington monument is fast getting to be a big thing. It is now over 300 feet high. When completed it will be the highest piece of architectural work in the world.

SCIENTIFIC PROGRESS.

Changes in Cruls' Comet.

Spectroscopic observations of the great comet, made by Commander Sampson, at the Naval Observatory, Washington, October 15th and 16th, showed the spectrum to consist of three bands. The brightest band was in the middle of the green, nearly corresponding to the "B" lines; the second was in the orange yellow; the third at the middle of the blue. The middle band was very bright, and sharply defined on the least refrangible side. The other two bands were of about equal brightness, but were much fainter than the middle band. Like it, their brightest portions were near the least refrangible side. No band sharply defined on both sides could be made out.

This spectrum is quite unlike the one observed when the comet was nearer the sun—a spectrum bright and continuous, with many bright bands, among which the sodium bands were particularly prominent. In the spectrum of October 15th and 16th there was no trace of the sodium band.

It was found that when the brighter portions of the bands were removed as far as possible from the field of view, the fainter portions were seen to extend themselves into an almost continuous spectrum. When the tail of the comet near the nucleus was examined, it was found to consist of a faint continuous spectrum, without any bright bands. The explanation of this great change in the spectrum is, that when the comet was first examined, just after it had passed the sun, the continuous spectrum was due to reflected light, while the bright bands were due to the incandescent vapor formed by the intense heat of the sun. The comet has now so changed its position with regard to the sun that the amount of reflected light has greatly diminished, and the comet itself has greatly cooled after its hot bath in the atmosphere of the sun. The beautiful silvery appearance of the comet is attributed to the preponderance of green light which it emits, as shown by its spectrum.

To account for the apparent separation of the nucleus of the comet into three or more parts on several days with subsequent consolidations, the hypothesis has been advanced that the nucleus is not a single body, but is made up of a cluster of independent parts, with a motion among themselves. The discovery by Dr. Schmidt, at Athens, October 8th, of a small comet near the great comet, and pursuing the same general course, tends somewhat to confirm the hypothesis of a broken or "cluster" nucleus.—*Scientific American.*

Oxygen from the Air.

A method of obtaining oxygen from air for technical purposes has been recently devised by M. Margis, of Paris. The principle is that of dialysis or diffusion under pressure. Atmospheric air being forced against a first caoutchouc membrane by suction, a mixture of about 40% of oxygen and 60% of nitrogen is obtained on the other side. A second membrane increases the proportion of oxygen to 60%, that of the nitrogen being reduced to 40. A third gives 80% of oxygen; a fourth 95%. M. Margis prepares his membranes by immersing taffeta in a solution containing sulphide of carbon (or light petroleum ether), spirit of wine ether and caoutchouc. After drying the taffeta has a fine layer of caoutchouc on it.

A bag of the membrane, with a framework of rings of galvanized iron wire is placed in a cylindrical iron vessel admitting air. It is connected by means of strengthened caoutchouc tube with the suction apparatus, which is (preferably) formed of a cylinder containing a series of conical cups with small spaces between. Steam is forced through these, and draws in the gas obtained from the first diffusion, passing on with it through a cooler, where the steam is condensed and the gas separated for its second diffusion. This latter occurs through a similar apparatus, except that the space round the bag is provided with a tube passing down into the water. The pressure can thus be regulated, and the superfluous gas let off. Four sets of the apparatus are generally used (as already indicated), and the final gas, with 95% of oxygen is collected in a holder.

THE CONDUCTIVITY OF WIRE—At a recent meeting of the British Association, Prof. George Forbes read an interesting paper on some experiments undertaken by him to ascertain whether or not it was true that a wire of twice the sectional area would convey an electric current of twice the intensity. It might be expected that if one wire would carry a current of one volt, two similar wires would carry two volts. This would be so if the currents were far apart; but Professor Forbes finds that when the currents are near together the radiating surface has to be taken into account. He finds by experiment that if there is a departure from the law of the square of the diameter, the law is almost proportional to the diameter of the wire. "If," he says, "you can carry a definite amount of current through a wire a millimeter in thickness, without heating it over a temperature of 150°, then if you want to carry a current twice as great through a wire you must have one or two mm. diameter, i. e., of four times the section." This result has an important bearing on the extension of electric lighting.

A Curious Accoustic Phenomena.

A correspondent of the *Manufacturer and Builder* writes to that paper as follows: I would like you to explain a very curious thing that I have noticed, if you can. About a week ago I was doing a piece of soldering, and carelessly laid my iron down, when I heard a clear humming noise, which would keep on for a while, then stop, and then commence again. I found at last that it came from the iron. To make sure I lifted it up, when the sound stopped. I laid it down again in the same place, the handle on the zinc-lined top of my work-table, and the copper bit resting on the edge of a lead anvil, when the singing noise commenced again. I have asked some friends about it, but they cannot explain it. I have tried repeatedly to make the iron sing for the satisfaction of the thing, but I cannot always succeed, though once in a while, when I happen to lay it down right, and the bit is the right heat, it starts off at once, and keeps it up for 5 or 10 minutes—a singing soldering iron.

To the above, the editor of the journal addressed replies as follows:

This correspondent has accidentally struck just the right conditions for performing one of the most curious acoustical experiments. The experiment in question is a familiar one in the physical lecture-room, where it is known as Trevelyan's rocker. The cause of the singing sound is the contact of two metals of different temperatures. The resting of the heated iron on the edge of the lead plate causes the lead to expand, raising a slight elevation in its surface at the point of contact; this slightly tilts the iron, and another contact is made with the lead, which expands and tilts it back to its first position. Thus a rocking motion is imparted to the iron. These vibrations will be imperceptible to the eye, but they follow each other so rapidly that they produce a musical note. Mr. Trevelyan, who first observed this phenomenon accidentally, like this inquirer, studied the subject carefully, and devised the instrument called "Trevelyan's Rocker," by which the experiment can be performed very satisfactorily. It consists of a bar of iron, one side of which is beveled and provided with a groove along its whole length, forming two sharp edges. The bar is provided with a long handle. When this device, which resembles a poker, is heated and laid across a block of cold metal, with the end of the handle resting on the table, it at once commences to sing, like our inquirer's soldering-iron. As the poker gradually loses its heat the singing becomes weaker and weaker, and finally ceases. By placing an iron rod, terminated by two knobs across the poker (thus weighing it), the weight of the rod causes the vibrations of the poker to become slower, and the rocking motion which causes the sound will be made visible to the eye by the movements of the rod and its knobs.

APPARENT SIZE OF MAGNIFIED OBJECTS.—Professor W. H. Brewer reported to the American Association concerning some experiments he had made upon the estimation by different persons of the size of images of objects seen through the microscope. More than 100 persons, of all ages, classes and occupations, gave very many different estimates. A common louse was used as the test-object, and the magnified image was projected at ten inches. By far the larger number of persons underestimated the size value theoretically given the image by scientific microscopists, which was about 4–66 inches. Two estimates were of only an inch; several were of more than a foot. One student likened the figure to a cockroach, another to a lobster. Mechanics and artesans generally overestimate. A draughtsman, who was accustomed to measure and draw all his work, after careful examination, said the image was at least five feet long! A professor of physics said he could make the image look of any size he wished.

CHANGES ON THE MOON'S SURFACE.—Prof. M. W. Harrington refers to two kinds of changes on the moon's surface which may be regarded as fairly established. The first is the land slides, which may doubtless be caused by the great alterations of temperature to which the moon is subject. Many of these slides may be easily recognized with good telescopes. The second form of change is illustrated by craters, which have been proven to be different in size and shape from what they were recorded by earlier observers. Many other changes have been suspected, but they are of a more uncertain and doubtful character.

THE MOON'S INFLUENCE.—Those who yet cling to the old-time faith in the moon's influence upon the weather may be interested to learn that so eminent a scientist as Sir William Thomson has recently felt called upon to declare that careful observation with the barometer, thermometer and anemometer have failed to establish any such influence, and have proved, on the contrary, that if there is any dependence of the weather upon the phases of the moon it is only in a degree so slight as to be quite imperceptible to ordinary observation.

THE MILK TREE.—A French chemist has analyzed the juice of the so-called milk tree of Central America, to the nutritive qualities of which attention was first drawn by Humboldt, and has found that the vegetable product really possesses many of the characteristics of cow's milk.

Mining Share Market.

There has not been much interest manifested in mining stocks of late, election matters attracting all the attention.

Assessments falling delinquent in November amount to $615,800, levied by 26 companies, of which Nevada mines want $376,800; California, $170,000; Arizona, $60,000 and Utah, $8,000. The assessments falling delinquent during the first 11 months of 1882 amount to $7,050,661, against $9,005,010 during the same time in 1881, $12,038,800 in 1880, and $13,921,100 in 1879.

The following companies had cash on hand November 1st: Andes, $350.55, Alta, $12,464.55; Best & Belcher, $16 328.19; Bulwer Con., $31,035.46; Bodie Con., $35,227.51; Bechtel, $2,994 90; Benton, $5,792.65; Chollar, $51,349 81; Crown Point, $22,473.33; Gould & Curry, $43,004.05; Hale & Norcross, $41,275 66; Lady Washington, $1,370 21; Northern Belle, $89,515,81; Oro, $1,827.21; Occidental, $7,128.77; Potosi, $17,552 85; Sierra Nevada, $43,773.18; Standard, $90,804.50; Tioga, $1,087.81. The following had an indebtedness: Albion, $122,786.03; Mono, $4,770.09; Savage, $7,029 85; Starr, $27,410.71 (old indebtedness $36 839.84); Union Con., $34,602.27.

A crosscut has been started westin the Sierra Nevada on the 2,700 level, about the middle of the 1,000 ft. of ground now open to exploration. It is intended to push the crosscut through to the west clay as soon as possible. As a considerable amount of ore was found on the 2500 level which ought to come down on the west side of the main north and south drift, the chances are good for finding ore in the present crosscut. Thus far there is no trouble with water.

There will be no other crosscuts started at present. However, in case of the west crosscut tapping a pocket of water, work will be stopped until it drains out, and meantime a crosscut will be started east. In this direction the chances for finding ore are as good as toward the west. It will be remembered that some large streaks of ore were cut through by the winzes, which streaks passed to the east and will come down a considerable distance to the east of the main north and south drift. Thus it will be seen that there will he no delay in the exploration of the ground. In case of a pocket of water being found at any point by any crosscut work will at once be commenced on another crosscut in the opposite direction, or at a proper distance north or south. The level having been thoroughly drained (as a whole) by the drift so long in progress through it, little danger from water is apprehended.

THE report of Lieutenant Healy, Commander of the revenue cutter Corwin, has been received. He gives an account of his cruise in the Arctic, and recommends that a line of soundings he made along the coast from Point Barrow to the Mackenzie river. He says that the Corwin has steamed within a short distance of Point Barrow, and found clear water as far aa he could see. He ventures the opinion that if he had only been prepared, and had any object in making the attempt, that he could have taken the vessel directly through to New York.

A BARGE loaded with 5,000 sacks of wheat was sunk at Princeton, Colusa county, Sunday night.

News in Brief.

AN earthquake in Wyoming on Tuesday.

THIRTY-FIVE registered distilleries in Los Angeles county.

THE material for the electric towers has reached Los Angeles.

DURING October 69 deep-water sail vessels arrived at San Francisco.

THE King of Corea has concluded a treaty of commerce with England.

THE London *Lancet* has taken up the warfare against cigarette smoking.

THE Author's Carnival for the San Francisco charities netted over $20,000.

NAVIGATION is closed at St. Petershurg, the river Neva being blocked with ice.

THE charges of misconduct in the affairs of the Carson Mint were not sustained.

THERE are 500 men in England whose incomes range above $2,000,000 a year each.

DESTRUCTIVE gales and inundations continue throughout Eogland.

A STRIKE of coal miners on the Monongahela river, in Pennsylvania, is in progress.

GREAT distress exists in County Clare, Ireland, owing to the failure of the potato crop.

THE Prince of Wales has consented to act as Chairman of the Longfellow Memorial Committee.

IT has been decided in Kentucky that horse-racing is not a game of chance in the sense of the Gaming Act.

THE strike among the Montreal ship laborers has ended. The men returned to work at the old wages.

THE steamer Dymphra, of the Danish Arctic exploring expedition, has been wrecked on the Siberian coast.

THE Supreme Court of Connecticut has decided that women are eligible to membership in the bar of that State.

BY the fall of the floor of the Town Hall at Rochester, N. H., Saturday night, 200 persons were precipitated into the cellar.

PRESIDENT ARTHUR declines to interfere in the case of Black Bear, sentenced to be hanged at Yankton, D. T., on the 15th inst.

A TERRIBLE conflagation has taken place at Uleaborg, in Finland, and enormous losses have resulted, stores, hotels, theaters, etc., being destroyed.

MELVILLE stated his belief that the Jeannette was entirely seaworthy, and fully capable of making the voyage. Referring to De Long's discipline, he said that it was very severe.

IN consequence of the outbreak of cholera at Mecca, quarantine has been establlshed at Port Said on vessels coming from Suez.

HENRY M. STANLEY has become thoroughly acclimated in Africa now, and eojoys excellent health there. He is broozed by the sun until he looks like an East Indian.

THERE is great distress at Alexandria among the victims of incendiarism who are waiting to be paid the indemnity. They have been compelled to appeal to private charity.

AT Buena Vista, Oregon a "hop pool" was formed, into which went about 50,000 lbs. of hops, which the pool has just sold for 62½ cents a pound. The hop crop of Polk county brings nearly as much as the wheat crop this year.

A LINE of steamships will shortly be established between San Francisco and Liverpool, which it is thought will divert some of the traffic of the Southern Pacific. One iron steamer of 3,800 tons has been launched for this service at Middlesborough, and another is being built.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

CALAVERAS.

BIG BLAST.—Calaveras *Chronicle:* Last Saturday a heavy blast was fired at the Bonanza hydraulic on Tunnel ridge, owned by S. S. Moser & Co. A powder drift was run into the gravel bank, which is something like 50 or 60 ft in hight, and one ton of powder put in, the drift filled and firmly packed with dirt, and the powder fired by means of fuse. The blast did splendid execution, shattering the bank from top to bottom, and for a distance of 30 or 40 ft into the hill. Mr. Moser expresses himself as perfectly satisfied with the result, and highly prsises the merits of the Vulcan powder, which, he says, he has found to be the best, and this is the general verdict of the mining men.

INYO.

THE MONTEZUMA.—*Independent*, Nov. 4: Billy Lake came down from the Montezuma mine yesterday. He reports that the machinery of the new smelter is all placed, and that the furnace is nearly completed. Teams are delivering coal and ore, and it is the intention of Supt. Orisweld to begin smelting operations on or about the 15th inst.

PANAMINT.—Supt. Pheby sends us the followiog: "Our mines are all looking first-rate. Have 9 chloriders here now, who help to keep the mill running almost constantly. The mill is in first-class order, and is doing good work. Since commencement of the present run we have shipped 4 bars of bullion valued at $4,900. Will make another shipment of $5,000 on the 1st of November, and continue to ship at the rate of $6,000 per week for some time to come. Our bullion contains considerable gold now, which helps out considerably. Bullion now running about .950 fine."

MODOCK.—Following is a general *resume* of operations since my last run: Ore extracted from Modock mines, 71 tons; from Black Warrior (my own mine), 110 tons, which, together with 102 tons of fine dust, make a total of 292 tons to date. Average samples taken daily from the Black Warrior give 113 ozs. On the 40 level have a 14-inch streak of soft carbonate ore, which is improving every shift. On the 80 level am stoping from 3½ to 4 tons daily of very high-grade ore. On the 150 level started prospect drift 12 feet ago; tapped ore body last night; average of face of drift, 69 27 ozs. Don't know as yet the extent of the strike, but will let you know next week. Davis & Mitchell are hauling coal, wood and iron. Will start up furnace by the 25th inst., if my supplies will justify me in doing so. Have discontinued work on all the company's mines until after this next run. Out of a force of 8 men working in the Lookout mine, 6 are now sick from lead poisoning, including our friend Martin Moe.

LOS ANGELES.

THE WINSTON MINE BONDED.—Los Angeles *Mirror*, Nov. 4: The Winston mine, in San Gabriel canyon, owned by Messrs J. B. Winston, S. H. Mott and others, was bonded yesterday for $30,000 to A. W. Barrett and J. H. Wheeler, of Lake county, two gentlemen who now take possession of the mine come from one of the principal mining districts of Colorado, and they know a good mine when they see it. Their bonding for $30,000 indicates what has been thought for a long time, that the Winston mine was a good one.

MARIPOSA.

A MINE LEASED.—Farmers' *Journal*, Oct. 28: Dr. W. H. Rice has leased for 3 years the mine and mill belonging to Messrs Costello gold and silver mining company, situated in Mariposa district, and has engaged the services of Mr. C. F. Leavenworth as superintendent. The Doctor proposes to put in the new machinery which the property requires for its due development, and will start for San Francisco on Tuesday next for purchase of engine, boilers, pumps, etc. It is the intention of the lessee to work the mine to its fullest capacity, and it is known to be rich, and only to need proper appliances to show its value; the new proprietor believes that he has a big thing.

NEVADA.

MINING SITUATION.—*Foothill Tidings*, Nov 3: The mining outlook, for this and the coming season, is, taking the views of miners who keep thoroughly posted, very flattering indeed. There is more prospecting going on in this district than was ever known before, but it is not on a large scale, for the reason that those who are engaged in prospecting have a limited amount of means, and can only work their ledges and mines as circumstances and finances will allow them. As a rule, those of our citizens who have means are interested in such business pursuits as to occupy most of their time and attention, and, therefore, have no spare time to develop the resources around here. That the ledges around here, and there are many of them, are well worth a trial there can be no doubt, and every business man in town who makes a fair profit for his year's labor and enterprise, should take an active interest in mining, and should aid every enterprise relative to mining, no matter how trivial it may seem, which may be inaugurated in our community. There have been quite a number of our business men who have realized this fact, and they have contributed liberally toward such enterprises. It takes money to open a quartz mine and place it on a paying basis. It takes a great deal of coin and a heap of economy and good judgment. There are innumerable ledges here that have never been developed, and probably never will be while the present generation lives; but, nevertheless, this part of the county is destined to become the best mining district on the Pacific coast. All we want is capital. Capital should be encouraged and coaxed into this mining district, and in case they do not strike a rich paying gold mine at the depth of a few hundred feet, it is not fair that said capital should be withdrawn and the whole county condemned as a non-paying district. This district is not half prospected; but by and by our people will see a town here second to none on the coast. It is nearly that way now. It will be that way at no distant day. Deep mining is what is wanted. The deepest mine here is nearly 1,300 ft. The Idaho is rapidly opening up its 14 level, and the 11, 12 and 13 levels in the mine have proven to be of great value. The 1300 level of the Empire has proven to be a better one than any ever opened up in that famous old mine. How do we know but what the majority of the ledges in this district may prove the same?

IMPERIAL.—This mine, on Deer creek, has its hoisting works in running order, and the mine is clear of water. The shaft is now down 160 ft. The company has made a purchase of the old Dartmouth mill, and that structure is being removed from its present site, and will soon be placed on the Imperial. The stock of the Imperial is owned mostly by Grass Valleyans, but very few shares being held outside of our town.

FORD & MULLEN.—This mine has lately had a crushing of 21 tons of ore, and it yielded $3,200. Mr. Mullen has disposed of his stock in the above-named mine, and Weissbein Bros. are the purchasers.

HARTERY.—The Hartery company, Stephen More superintendent, is sinking its shaft on the ledge. The shaft is now down about 600 ft, and is in good ground. The ledge is from 12 to 18 inches in thickness, and the quartz from it looks encouraging. This mine is employing 6 men in the underground workings, and this force will be increased as soon as the mine will allow. As depth is attained in the Hartley the ledge and all its surroundings seem to improve.

HUDSON & Co. have recently had a crushing of ore from a prospect hole situated near the Lowery ground. Five loads of ore were taken from the shaft, and it yielded $48 per load. The hill where this claim is located seems to be full of quartz stringers, and all of them are rich in gold.

EAST EUREKA.—Operations at the East Eureka are very brisk. The mill was started up on Wednesday last on company rock from the lower level, and the rock gives promise of a good yield. The ledge in this level has gradually improved in quality, and is looking better now than it has ever looked before. Since the crushing now going through the mill was taken out, a still better ledge has come into the face of the drift.

PLACER.

DEPRESSED.—Placer *Herald*, Nov 4 Dutch Flat and Gold Run, two districts of Placer county, in which are situated hundreds of thousands of dollars' worth of mining and ditch property, are to-day comparatively stagnant in consequence of the cloud of uncertainty, that, owing to this debris agitation, hangs like a pall over the mining regions of the State. Other districts of the county are in but little better condition. Auburn has felt this stagnation of one of our great industries this last summer very sorely, notwithstanding it has been said by certain wise men that it would not hurt Auburn; and all the State feels the depressing effect more or less.

PLUMAS.

CRESCENT.—Plumas *National*, Nov. 2 In company with Mr. A. Hall on Monday, we made a trip to Crescent and Greenville, and while in the first-named place took a look through the Crescent mine. Mr. T. Davis, the superintendent, showed us around. The new strike is in the ground between the old Crescent and Pet ledges, and runs almost east and west. The work has developed the lode for some 60 or 80 ft on the vein, and to a depth of about 50 ft. This ledge—which should be called the Davis ledge—has increased from a 6-inch vein on the surface to about 18 or 20 inches at the lower workings, and the amount of gold which it carries is certainly wonderful. So far, the mill process has shown it to be worth from $30 to $40 per ton, and at the bottom it is now certainly worth more than that. Seventy-five tons now in the Crescent mill will probably yield $50 per ton, and part of it would go three times that. About 30 men are employed by the company, and an increased force will be put on when necessary. One-half of the old mill—16 stamps—is being refitted, and will soon be in working order, and the owners will have no reason to regret that they have started on the "new departure." There is no "fancy work" in the management, but his plan seems to be to make the improvements strong and substantial, and get the rock out and gold out of the rock as cheaply as possible.

CALIFORNIA PROSPECT COMPANY. At a meeting of the stockholders of the California prospect company, held at Quincy one day this week, the following named gentlemen were elected as officers: Geo. T. Van Doren, of Boston, President; E. A. Halstead, of Oroville, Vice-President; O. B. Smith, of Huron, Ohio, Secretary and Treasurer; E. F. Parsons, of Quincy, Cal., Superintendent; J. H. Wicknam, of Huron, Ohio, elected as a member of the Board. The company is operating in Newtown district, about 2 miles from Quincy, and have some very valuable mining ground there. They are pushing the prospecting work in some of their mines, and getting some good pay, and in a short time will put on machinery which will facilitate operations to a considerable extent.

SAN BERNARDINO.

GRAPEVINE DISTRICT.—Los Calico *Print*, Nov. 1. The Lone Belle copper mine, located in Grapevine district, 3 miles from the Home station, at Fish Ponds, 4 miles from Calico, is now being worked by Mr. Simmons and R. B. Johnson. They are sinking and taking out some excellent ore. The vein matter appears strong, indicating a valuable piece of property. The claims adjoining the Lone Bells, viz., the Silver Lead, Black Lead and the Eclipse, were bonded to Col. Barstow recently for $20,000.

SIERRA.

SHUT DOWN.—*Mountain Messenger*, Nov. 2: The Jim Crow quartz mill has been shut down for the winter. They had in no supplies and were otherwise not prepared for work. Several men will work in the ledge until spring, when the mill will be again started.

JEROME YORK is building an arastra in Slug Canyon on his quartz ledge. If the storm will allow him to complete it, we think he has a good thing

FORREST CITY NEWS.—*Sierra County Tribune*, Nov. 2: The Rainbow company is still pushing things ahead as fast as possible, and the rock continues to pay very rich. The Savage company is pushing its tunnel ahead as fast as possible, and is laying in supplies with the intention of carrying on work this winter. Supt. Smith, of the Lafayette Hill mine, has received word to close the mine down. This is very unfair to Mr. Smith, as he had just got the tunnel in and was getting ready to raise up, when it is thought he would strike gravel. The Bald Mountain Extension company in its last upraise found a very fine prospect, but the bedrock is pitching, and they are evidently on the edge of the rim. They will start the tunnel ahead soon, and will probably reach the center of the channel in 100 ft.

TO BEGIN WORK.—H. Taber, of Gibsonville, recently returned from San Francisco, where he had been perfecting arrangements with parties to open up the Taber gravel mine at Gibsonville. It is the company's intention to push ahead the tunnel—which is already in a long distance—for the back channel, which Mr. Taber thinks will be reached by next July. Operations will be commenced shortly. The recent rich developments made in the old Union mine at Gibsonville have revived the mining interests of that section to a great extent, and everybody looks for a genuine "boom" by next summer.

NEVADA.

CHERRY CREEK DISTRICT.

EXCHANGE.—White Pine *News*, Nov. 4: In many of the drifts the showing even now is very promising, and the small force at work—five men in all—were taking out some very fair average ore. In half a dozen places more or less of the same kind of ore was visible. We have never seen a prettier or more regular foot-wall in any mine. The vein appears well defined, with a pitch to the northwest, the formation being porphyry and quartzite, which is always considered the home of silver. Above the water level we saw ore enough in sight, when taken out and crushed, to more than liquidate the company's indebtedness, and of course no one can tell how much more will be found by following up the ore veins now in sight. Manager Guild so far has managed matters admirably, and has already paid $14,000 to the creditors, besides his running expenses. There is no mine in this district that has produced richer ore than the Exchange, and it has so far been prospected barely below the grass roots. With a live, energetic company, and such good management as Mr. Guild has displayed during his stay here, the Exchange property can be made one of the most profitable mining properties in eastern Nevada.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Nov. 4: The main drift on the fifth shaft level continues in ground of the same character as last reported, and has been extended 17 ft during the week. Crosscut No. 1 on the same level has passed into a heavy clay formation. The crosscut from the main drift on the third shaft level, in which there is softer ground, has been extended 10 ft, the total length being 93 ft. There is some improvement on the second shaft level in the west part of the mine. Some ore of excellent grade is being taken out at this point. Nearly 70 tons of ore are being extracted and sent to the mill daily. Mill No. 2 is running steadily and doing excellent work. The bullion shipments have amounted to $23,669.27 on November account to the 3d inst., the total yield for October being $100,771.60.

MOUNT DIABLO.—A streak of $60 ore has been developed in the east drift from winze No. 1. The west drift is showing ledge matter, and looks encouraging. Winze No. 2 is down 56 ft, and has a strong ledge of low grade in the bottom. The south crosscut above winze No. 4, between the second and third levels, shows some 9 inches of ore assaying $120. The west drift from the north crosscut on the third level has developed a small streak of $50 ore. A small body of ore has been encountered in the north crosscut from the east drift on the first level, that assays $40 per ton.

ESMERALDA DISTRICT.

WORK PROGRESSING.—*Herald*, Oct. 30: Work on the mill is progressing with more than usual order and rapidity. The foundation pit for engine is nearly completed, the boiler and furnace in place, and grading for batteries, ore bins and rock crushers well under way. Many of the heavy timbers are framed, and the erecting of the main portion of the mill will commence next week. Superintendent McIntosh is tireless in his attention to all matters under his charge, being ably assisted by Mr. Barton, supervising builder.

A LUCKY BREAK. Last week, while unloading one of the pans for the mill at Gregory Flat, it dropped to the ground and broke, the whole bottom coming off. In examining the wreck closely, it was observed that there was an old crack in the pan, and a look at the false bottom beneath disclosed the fact that both quicksilver and amalgam to a considerable amount had worked through the old crack and found lodgment there. Mr. McIntosh has already cleaned up about 150 pounds of quicksilver and a considerable amount of amalgam—enough in all, he informs us, to pay for repairing the break.

EUREKA DISTRICT.

ALBION.—Eureka *Sentinel*, Nov 5: Punctually at 3 o'clock yesterday afternoon, furnace No. 1 was started at the Albion mine, and up to the time we left Mr. Leyshon's hall, at midnight, the furnace was running as well as could be asked, and was pouring bullion out rapidly. The works throughout are complete, and within another week furnace No. 2 is expected to start. The two have a smelting capacity of 100 tons per day, and when the dust chamber and flue to carry off the fumes is completed, which is now in process of construction, these works will be in all things more complete than any other works on the coast. No expense, time or labor has been spared by Messrs. Prescott, Scott & Co., of San Francisco, the contractors for erecting the furnaces. They are complete in every way, and are a credit to the builders and the company. With these furnaces the Albion Company can certainly mine and smelt ore cheaper than any other works in this section of the State. The whole system, thanks to E. N. Robinson, the superintendent, is perfect. Advantage has been taken of every facility where the location offered, and from the mine the ore, the coal and mining timbers leave the power either of steam or horses. Everything is down hill. Gravity is used instead of power. The bullion alone is transported up hill. The system of roads, including the railroad, when finished, is complete, affording access to every part of the works. The end of a four years' struggle, coupled with a large expenditure of money, was practically reached yesterday afternoon, when the first bar of bullion was turned out from the furnaces; and notwithstanding all the sneers and doubts expressed by the enemies of the Albion Company, we have not a doubt but that the furnaces will continue to turn out bullion until it becomes the leading producer of the district. Its ore deposits are very large and daily developing, and we cannot think of anything to prevent the company from being a success in all ways.

JACKRABBIT DISTRICT.

AT WORK.—Pioche *Record*, Oct. 28: Jackrabbit District is the only mining district in which work of any amount is doing at present. The Day company continues working a full force of men, who are kept busy running drifts and sinking. In the Pay-Day mine the cutting out for the 200-ft station is going on, and after it is completed a drift will be run, and the sinking of the shaft resumed. At the bottom of the shaft, where the station is being made, it is all opened fissures, the formation being black spar and iron, sprinkled with small spots of ore. The Terror mine, the property of Williams & Craig, is being worked in systematic way, the ore holding its own as sinking progresses. This mine has a remarkably fine showing. There are several claims, all displaying ore, which give great promise and make the owners happy. The outlook for Jackrabbit District is much brighter than it has ever been.

LEWIS DISTRICT.

BETTY O'NEAL MINE. Lewis *Herald*, Nov. 3: The south level 260-ft station has been advanced 6 ft, and an upraise of 12 ft made during the week. This level is in ore the whole distance, and the uprise shows the same character of ore throughout. The crosscut has been run 14 ft during the week. Considerable ore is being taken out, and the prospects of the mine were never better than at present writing. There has been no increase of water as the level is driven into the hill, and it is supposed that the main water vein has been already cut. Good headway is being made with the tank station, and sinking will shortly be resumed.

EAGLE MINE.—A. P. Courtner, manager of the Highland Chief and Eagle mines and mills, has received instructions to move the Highland Chief hoisting works and air compressors to the Eagle mine. Work will be commenced right away. The tunnel will be cleaned up preparatory to letting contracts.

MORNING STAR.—Mayo incline advanced during the week 10 ft; total depth, 309 ft. The bottom is in 2½ ft of good ore. As soon as the contract is completed in Mayo incline will then raise from head of Mayo incline to surface and place hoisting works there. All hoisting will then be done through that incline.

SUMMIT SPRINGS DISTRICT.

SMELTZER COPPER MINE.—Lewis *Herald*, Nov, 3: Last Wednesday, in company with U. Mayo, one of the owners, we visited the Smeltzer copper mine at Summit Springs mining district. The lode is prospected by a shaft 120 ft in depth; a crosscut has been made at the 60-ft level, and the ledge proven to be over 14 ft in width. Another crosscut has been started at the 120 ft level, but had not at the time of our visit reached the hanging wall. The ledge in the surface can be traced for several thousand feet. Assays from the ledge show the property to be a valuable one. Mr. Smeltzer has a very fine ranch near the mine, and is making many improvements. He has constructed a dam, and intends stocking the lake with fish from Sacramento. We were handsomely entertained during our stay by Mr. and Mrs. Smoltzer, who made our visit a very pleasant one.

ARIZONA.

TURKEY CREEK.—Cor. Arizona *Miner*: This is destined to be the camp of the country, for the following reasons: The mines commence to show themselves on the divide of the Assayampa, and continue until you reach the Bradshaw. There is plenty of water and good timber. It is the best site for a town that can be found in this section of the mines, and the number and quality of the different mines that are being developed in this immediate vicinity guarantee a town of some importance to supply the wants of the large number of men necessarily engaged in the working of the same. The Goodwin mine has been shut down for the past few years, but now it is being worked under the charge of Mr. George McCann. At present the new shaft is only 60 ft deep, but will be pushed down rapidly now, as they have a whim in place and everything ready to prosecute the work rapidly. The Holmes has a shaft 82 ft deep, showing ore all the way down it. This mine belongs to Messrs. Holmes & Hatz. The Homestake is one of the boss mines of this camp. It has a vein of mineral that varies from 4 to 18 inches. Two tons of this ore worked at the Tuscumbia mill gave $455 to the ton. An extension of the Homestake is the Lincoln, and is the same as the original location throughout. It is owned by Messrs. McAuliff and Fitzgerald. In proceeding down the gulch and passing the ranch of Mr. Randolph, is the works of the Hidden Treasure. This company is doing great work for this camp, under the management of Mr. Chases as superintendent and Mr. McAuliff as foreman. There is in process of erection a 10-stamp mill, a saw-mill and other buildings. When Mr. McAuliff came from the East he brought a complete outfit of Ingersol drills with blasting attachment,

COLORADO.

CITY GROVE.—*Colorado Miner*, Oct. 25. Messrs. Steve Edwards, B. R Elliott, Robert Buchanan and Eugene Jones, the owners of this recent location, have run in, 35 ft below the discovery adit, a 65-ft crosscut, which last week struck a 15-inch vein of galena, gray copper and iron. They are now driving ahead on the vein and taking out considerable ore.

IMPORTANT STRIKE.—On Tuesday of this week an important strike on the Eagle Bird, one of the numerous leads of the Pelican-Dives company, was made by Messrs. Lamphire & Co., lessees. They have been running a crosscut south from the 2d level of the Pelican lode, and at a distance of 55 ft thereon they struck 3 inches of rich galena ore, assaying 200 ounces. They are 240 ft below the surface, on virgin ground, below which no explorations have been made On Thursday 2 men, in drifting on the strike, took out 19 sacks of ore. The surface production of this lode has been very rich. This discovery proves the continuity of the vein, and it is confidently expected to prove as valuable as some of the other lodes of this company, which, in early days, made Republican and Sherman mountains famous all over the country

CHAMPION MINE SALE.—The Idaho Springs *Avalance* says that Mr. N. Sands, agent for the English syndicate which owns the Donaldson and other mines located in Clear Creek county, has purchased the Champion mine after a prolonged negotiation. The amount paid for the property is not less than $200,000.

SUMMIT CON. M. CO.—Away back in 1860, Gen. Russel F. Lord purchased the Summit lode, on Griffith mountain, or, as with old-time memories, heinsiste upon calling it Summit mountain. Since that time the General has added other property, which new consists of the Summit, Precinct and Fort Jarvis lodes, which forms the consolidation named above. The General, with his brother, Major Lord, and Gen. Crook, both of the regular army, are the sole owners, and is not a wild imagination that predicts something like a bonanza possession for those gentlemen if the present indications hold out.

IDAHO.

NARROW GAUGE MINES.—Wood River *Times*, Oct. 28: The Narrow Gauge mines, on Deer creek, are opened to an extent sufficient to prove them veritable bonanzas, but on account of the lack of teams, the ore extracted is accumulating at the mines. Under such conditions, rapid extraction is prevented, as the ore cannot be sent to market. Superintendent Clark is a thoroughly active, practical manager, who has developed the property rapidly under adverse circumstances. He has shipped continually, as long as teams could be secured, to transport the ore to Hailey, but, owing to the impossibility of securing grain, the teamsters have abandoned the contract of hauling it. Over 100 tons of high-grade ore are now sacked at the mine, and 400 tons more are on the dump unsacked. Of the latter, considerable will require concentration, and must be jigged before being shipped.

BULLION.—Ketchum *Keystone*, Oct. 28: Several teams have gone out with bullion during the week, yet something near 200 tons still remain at the smelter. Col. Miller is confident, however, that little difficulty will be experienced in securing transportation for all the bullion that may run out this fall. The outlook bearing the Vienna mill machinery to its destination will move over 100 tons of the precious freight upon its return.

We learn from Dr. Cortright, who called on the *Keystone* Wednesday, that the Columbia and Beaver mill made its most successful run on Lucky Boy ore just before shutting down. Although the mill is closed down for the winter, operations will be resumed early next season.

THE ONTARIO.—Developments in the Ontario continue in a very favorable manner. The vein pitching to the northeast at an angle of 73 degrees with the horizon, has been re-struck in the breast of the main tunnel, which had raised its course from a position under the vein. It appears well, about 30 inches wide, consisting chiefly of rich-grade galena, while carbonates of good value fill out the vein; and it is accompanied by a regular and solid foot-wall, while the hanging wall, though regular, is yet a soft composition of porphyry and granite. A recent assay of a fair galena sample weut 206 ounces in silver and 73 per cent. lead. The work is now getting into deep and solid formation.

MONTANA.

WATER JACKET.—Helena *Independent*, Nov. 2: The smelter of the Gregory Con. Co. is running satisfactorily with its enlarged water jacket, and turning out a much larger product of argentiferous lead than formerly. During one of the days reported, 18,300 lbs, or over 9 tons, was produced, and the value is slightly increased as compared with the previous run. For a time the cullings on the old dump were used to a much larger extent than now, and while the property was large it was not equal to that realized from the ore now coming from the mine, as the rich grades, as well as the poor, are utilized at the works. A much larger quantity of prepared ore was on hand at the beginning of the present run than ever before, and new roasters have been added to such an extent as will secure continuous work for the furnace. The gross value of the furnace product will reach $3,000 per day for a large part, if not all, of this run.

NELLIE GRANT.—The hoisting works are now completed at the Nellie Grant mine, and on the 1st of November they will be put in operation. The condition of the mine when work was stopped on account of water some weeks ago was such as to warrant the expectation of a large output of ore when work on the vein is resumed. During the last fortnight there have been two 6-mule teams steadily at work hauling the first-grade ore from the mine to the reduction works at Wickes. Should the weather continue favorable for a few weeks longer, the quantity of ore taken out and marketed will aggregate enough to materially assist the Nellie Grant company in its winter's operations, and we are informed that thus far the character of the mine's output has been fully up to the expectation of the promoters of operations there.

COMET.—It is said by these who have for a long time been well acquainted with the Comet mine, that the quantity of ore exposed in that property at present was never exceeded at any time in its past history, and the grade of the galena is better than ever.

BANNER.—The Banner mine, adjoining the Gregory, has been thoroughly cleaned out and put into workable shape with reference to future development. Owing to the fact that the product of the Gregory was so large as to render it unnecessary to buy any ore for the reduction works, that taken from the Banner is yet on the dump. But the work done has more than paid the stockholders of the Banner company by not only piling up a large dump of the mineral where it can be seen, as proof of what the property can do, but also throwing a large amount of reserves in sight, to be utilized whenever occasion may demand, and now the mine is timbered and in condition to be examined whenever it is desirable. There is no reasonable doubt as to the value of this mine, and it is to be hoped that it will not be allowed to remain idle again under any circumstances.

MINERS are busy representing their claims at this season of the year, or securing government titles to them whenever the conditions are such as to allow it, and there is consequently much activity apparent among them just now.

NEW MEXICO.

SANTA RITA.—*New Southwest*, Oct. 28: The Santa Rita Copper and Iron Co. has started up its new machinery, and the mill is now making its regular run in a very satisfactory manner. The concentrating work is found to be a most perfect. It was found, owing to the extreme softness and friability of the porphyretic rock carrying the native copper, that it powdered up into the stamps so that a considerable waste was occasioned in the concentrators. This has been entirely obviated by the use of Cornish rolls, the company having put in three sets in place of the stamp batteries. The company has put in elevator cages in its two shafts lately at the Romero mine, each shaft being worked by an independent action, and by which some 400 to 500 tons of ore per day can be hoisted. It has also a complete outfit of ore cars, holding about three-quarters of a ton each, which, being loaded in the different levels of the mine, are rolled upon the elevators, which hoist to the high tramway of the shaft. They are then conveyed over a track to the upper part of the mill, and from thence through the rock breakers to the rolls and on to the concentrators, making a mechanical and automatic method from the mine to the tailing dump. By this continuous method a great expense in hauling is saved, which is of much importance in the economy of mining. The concentrators, 40 in number, with the Evans slime tables, are practically the same as used at the Lake Superior copper mines, having, however, a trommel attached for the accurate sizing and grading of the crushed ore before it goes to the concentrators. The whole machinery is now running splendidly, and if anyone wishes to see the most magnificent and complete mining outfit in the western country, and in fact the best in many respects in the United States, we invite him to inspect the mining and milling plant of the Santa Rita Copper and Iron Co.

NOTES.—A large force of men is working on the Colossal mine in the black Range, and very rich ore is now found..... It is reported at Central City that Mr. Terry intends to erect a large smelter at that place, for the reduction of the ores of that district and Hanover..... A rich strike, that may develop into a bonanza, has been made at the head of the Dry Polonas by Smith and Montgomery. The ore is found in a porphyry formation, and carries a large amount of silver..... The Pius IX mine, at Central City, belonging to E. Stine, S. Extine and Henry Woods, shows at the bottom of its 75-ft shaft a true fissure vein, two ft in width, carrying ore that runs 500 ounces in silver and about 40 per cent. in lead..... Seven thousand ounces of silver were shipped through this city on Thursday last by the Naiad Queen M. Co. of Georgetown. They had five thousand ounces left after the shipment that had not been melted into bricks. They shipped 10,000 ounces last week, and their average production is about 27,000 ounces per month.

OREGON.

NOTES.—Jacksonville *Times*, Nov. 4: Good weather for miners..... Superintendent Eanis, of the Sterling mine, has had the long line of ditch cleaned out and is nearly ready for business..... Welch & Co. began work in their Blackwell District at work, and are crushing quartz taken from the old Wallace lodge..... Several tons of quartz have been taken from Bolt & Co.'s ledge on Steamboat to the mill at Horsehead, Josephine county, for testing..... W. A Johnson is still at work on the old Jewett ledge, in the expectation of striking a bonanza yet. His perseverance is worthy of reward..... John Haviland, of Canyon creek, Josephine county, has his mine in readiness for the pipe and giant, saying at Crescent City..... The prospects for a good mining season seem better than ever. The early rains have thoroughly soaked the ground, and not much more is needed to afford a sluicehead..... The two quartz mills now running in southern Oregon have been needed, and will prove of great convenience and importance to those owning ledges, inasmuch as it enables them to ascertain their value in a thorough and scientific manner..... The Blue Gravel M. Co. has concluded not to work its mines at Galice creek any more for the present, and the English Co.'s diggings will also lie dormant this season, owing to some difference between the stockholders in England, we learn..... Wm. Bybee and A. H. Carson are now working a ledge that paid enormously several years ago and was abandoned after a protracted lawsuit. It is situated near the old Jewitt ledge, and Mr. Carson assures us that there is every prospect of its proving first-class property..... Wm. Bybee, who returned from Josephine county a few days ago, informs us that the mine he is interested in with Messrs. Newman and Hawkott will soon be ready for work. The ditch, which is ten miles long and required 40,000 feet of lumber for fluming, is nearly completed..... Jas. Hanseu, a first-class miner, and who was recently appointed receiver and superintendent of Wimer & Simmens' mines near Waldo, took charge this week, and is putting them in shape for the season's run. There is already a full head of water in the ditch connected with the diggings..... C. W. Burrage, of Portland, who is prospecting the county for iron ore with Mr. Pomeroy of Oswego, called on us yesterday. He informs us that the indications for extensive deposits are favorable. Owing to the inclement weather, they will be obliged to suspend their present search before long.

UTAH.

NOTES.—*Southern Utah Times*, Nov. 2: On Thursday several hundred tons of earth broke away from the Bonanza mountain, and fell down into the opening made by the caving in of the original workings of the Horn Silver mine, 2 years ago..... The First South Extension Horn Silver mining company (the Lulu) discontinued work last Saturday. Supt. Ryan will not resume work, he says, until hoisting machinery arrives, as the whim is of little use under the circumstances..... The Horn Silver mining company, of Utah, makes a very good showing for the past fiscal year, which ended June 30th. The estimated value of ore smelted was $1,729,528. Total receipts, $1,743,762; operating expenses, $984,188; net profit, $759,574..... The Bassick mining company, with which the principal Horn Silver folks are identified, is putting a steam pump on the Golden Gate property, at Querida, Col., for the purpose of taking the water. The Golden Gate company will work one shift in the daytime, and the Bassick will pump the water out at night.

STORMONT.—Silver Reef *Miner*, Oct. 28: The Stormont company has, so far, during the present month, had a successful run. Bullion shipments are in excess of any previous month for at least 6 months, and present movements go to show that the property is, in every way, managed with satisfactory results. Eight or ten teams are constantly engaged in transporting ore of a good grade from the mines to the mill, some 6 miles distant, on the Virgen river.

BARBEE & WALKER.—Owing to the absence of Mr. E. T. Gillespie in the East for some time, pay-day has been delayed for 2 or 3 months till his return. The property of this company is steadily improving in value as new developments are being made below on the different levels. The company is making regular shipments of bullion through Wells, Fargo & Co.

COPPER MOUNTAIN.—Mr. Shaw, just in from Copper Mountain district, called at our office this morning and reported the Copper Mountain mine in a prosperous condition. Large amount of fine quality of ore is being extracted daily, and they will soon commence running out bullion. As depth is attained in the lead the ore is running into silver grade. The owners of the mine have made a visit to the property, and are well pleased with future prospects, and will push the work with a vim.

MARYSVALE.—Cor. Salt Lake *Tribune*, Oct. 28: There is considerable excitement over the strikes of rich ore in the Crystal, Clyde, Bushoy, East Gut, and other mines in Cottonwood canyon, all of which are contact veins, lying between quartzite and lime, and bid fair to be veritable bonanzas when developed. The Crystal has about 1,000 tons of good ore on the dump, and is now beginning to strike it richer. A road is to be built immediately to the mouth of the canyon, and a quantity of the ore will be shipped to Salt Lake and thoroughly tested. Machinery for working the Crystal mineral is what is wanted, and should be erected. More men are to be put on at once..... The Clyde mine has struck it big. The ore is grey copper, carrying a good percentage of silver. This mine will be worked by a small force through the winter months..... The Bushey mine is being worked under a lease, and some very rich ore is being sacked for shipment to Salt Lake. The vein is of good size, and the owners say it is of sufficient richness to pay well if the ore could be worked in this vicinity..... The last, but not least, worthy of attention is the Gen. Butler, a late discovery, made by Thomas T. Butler, of Silver Reef, who is interested in some of the valuable ground of the camp. The Gen. Butler is a fissure vein, running northerly and southerly, crops on the surface for at least 800 ft, and is 10 ft wide. We saw one piece of the ledge knocked off that would weigh 800 lbs., which, when broken, showed horn and brittle silver in paying quantities through the whole of it.

The Denver Exposition—No. 12.

[Editorial Correspondence.]

Having complsted our description of the mineral districts of Colorado, as shown at the Denver Exposition, now

"Dakota comes! What varied wealth of mount and plain
she brings!
How vast! Athwart the coming years a go'den light she flings;
Her mines exhaustless, soil the richest, healthful, balmy air,
She holds to give and gives to bless—her bounties all may share!"

The Black Hills of Dakota are situated in the wsstern portion of that Territory, a small portion of the "Hills" crossing the lins into Wyoming Territory. Thsy cover an extent of country ahout 100 miles long hy an average width of 50 miles, embracing an area of ahout 5,000 square miles. Ths mines, howsver, are contained within a csntral portion of ahout one-half that area, within which are a great numher of minsral veins and vast tracts of gold hsaring gravel which will continue to he worked many decades.

The Geology of the Black Hills.

The "hills" rise from a snrrounding plain, like an island from ths sea, in a oviform shape. An egg lying on a level surface, with the smaller end pointing to the northwest, fairly illustrates ths form of ths mining districts of ths Black Hills as they would appear to a party passing over it in a balloon—Dsadwood and Lead City hsing at the northern extremity, Custer at ths sonthern, and Rapid City near its center. Ths "hills" have evidsntly hssn projected upward through the surrounding plains, which consist of potsdam sandstone, lime, coal, etc. In ascending ths mountains, and just heyond ths foothills are reachsd, there is a shale formation in which coal is sometimss found. Ahovs this is a great vein, a circle of carhonate of lime running entirely around the mountains, and some five miles in hrsadth, overlying and abovs which is a narrow formation of gypsum, from which the finest of plaster of Paris is made. Passing over and above the lime we enter the slats and granits formation, ths latter of which forms ths uucleal or csntral point of upheaval. Across these successive laysrs of lime, slate and granits, in a hroad hslt, extsnding nsarly southsast and northwsst, and ahout 60 milss in length, occur the mineral veins which have made ths Black Hills so famous for their yield of the precious metals. Ths hills ars covered with heavy forests of pine, and ars intersscted hy numerous streams of never-failing water, along which are many hsautiful ravinss, valleys and parks, which are everywhere heantified hy groups of evergrsens, interspersed with grassy lawns. Around the whols ars extensivs plains, reaching far out into the distsnce, with the finest areas of wheat lands on the continent. It is confidently claimed that no other mineral country in ths world can show such unsurpassed facilities for agricultural supplies. The country all around the Black Hills is

Filled With Wonders.

And presents a most inviting fisld for thoss engaged in paleontological researches. Hsre are found in great profusion the fossil remains of the monsters of the early agss of the world—petrified tortoises from 8 to 10 feet in circumference; fossil honss and tusks of such huge dimensions that whsn compared with thsin the elephants of to-day should he recorded as lilipntisn in size. So numerous have hssn such finds that the country hsrsahouts has heen most appropriatsly called ths Great Bone Lands. "Nowhere else known," writes a contsmporary, "have the tremendous forces of fire, flood, frost and pulverizing glaciers outwrought such wonderful natural conditions. In places elevations tower up with all the characteristics of view of a great city sesn in the distance; presenting pleasing conceits of parks and avenuss and stsspled edifices. In othsr directions the appearance is that of a vast field covered with colossal hay-cocks; and then a change of the line of vision discloses to the fascinated ohserver quadrangles, parallelograms, diagonals, octagons and every other conceivable geometric form—all as clear cut hy the outlining open spaces hetween as if they had heen modeled hy the Titans for flower-plats. Still, they embrace great sweepe of excellent grszing lands, the stock raisers psrsistently demanding the extinguishment of the Indian title, until at last their efforts have heen crowned with sncess."

The Early History of the Bisck Hills

Is full of romance and peril. It is known that a party of emigrants from the great procession which crossed the plains in '49 found their way into these hills. The remains of two old cahins in the vicinity of Deadwood, with indications of rude prospecting, hlasted and hullet-scarred trees, now grown over, a chain deeply imhedded in a growing pine, and a niece of hoard with a partly ohliterated record, confirm the theory and add evidence to the story of the Indians that such a party did go in there and were soon after all murdered hy the natives.

Indian Superstitions.

It is said that no Indian ever ventnred very near the summit of these mountains, for the reason that they have a superstitious helief that the Great Spirit resides up there, and that at times he clothes himself with clonds and fire and speaks in the thunders. It was thought to he daring sacrilege to pitch the tepe or scent the deer in such a sacred place. To their superstitious minds every peak was a Sinai; and while tiey would not themselves go there, they natnrally considered it a religious duty to prevent white psopls from invading the Pah-Sappa, or "Dark Forests," where their deity resided. With what enthusiasm and fisrce detsrmination they tried to perform what they considersd a sacred dnty the scores of gold seekers who fell in ths first attempts to reach that region most fully attest. Through all coming time thsir msmories and graves, wherever known, should be kept fresh with flowsrs and evergreens, as honorsd pioneers and martyrs in opsning up a road to wealth and prospsrity for those who are now, and for many years to come, will continne to profit hy their sufferings and death.

The First Permanent Mining Operations

In the Black Hills was commenced in the spring of 1875. The first town laid ont was Custer City, in August of the same year. For some two or three ysars previous to that time Government troops had hesn ordered to keep miners away, and to rsmove those who had already located there. But in spite of all precautions small companies would, now and then, elude the militsry and gst into the minss. The success which generally attended such adventures crsated snch a rush and dstermination that the Governmsnt was finally ohliged to reconsider its dstermination and give way to the thronging thousands which rushed thither.

With the opsning of the spring of 1876 ths emigration thither was very large, and that and the year following were the hey-day of placer mining in the two famous Whitswood and Deadwood gulches, hoth located in the northern part of the "Hills." Still Indian attacks were freqnent, and trains of smigrants or supplies could only come through hy using the grsatsst vigilance. Miners had to work

With Their Rifles by Their Side.

The Indisns were mostly under control of ths famous Sitting Bull, and hy them nearly svery milsstone on the roads to ths Black Hills, and the roads and trails among those mountains, hss heen marked hy an untimely grave. In many instsnces whols parties were cut off. The writsr has a cherished family keepsake, a photographic picture of a group of five young msn, all at the time it was taksn in the prime of lifs. They stsrted from this city for the Black Hills, hut nsver arrived there. The newspapers ahout that time reported ths finding of five hodiss, thoss of a party evidently killed in camp while en route. No douht the lifsless rsmains there found and huried ones formed the happy group which sat for the picture now hefore us as we writs. But in

The Search for Gold

Msn will endure and will hszard evsrything. No ohstaclss, which it is in the powsr of man to overcome, will har the way in such venturss. Ths rssult has heen that within the last five ysars not less than 1,725 stamps have hesn put in opsration in ths Black Hills. These include a 10-stamp roasting and amalgamation mill at Galsna, a 20-stamp amalgamation pan mill at Bald mountain, to which may hs added a 30-ton smeltsr, at Galsna, for treating the galsna ores of that district.

We have no statement at hand as to the general aggregats of ths precious metals taken out from the mines of this locality. The only rsliahls statistics which we have in this direction is from ths rsport of the Homestaks and associated companies, which comprise hut a mers minimum of either ths arsa or the numher of producing mines, although thers is no question hnt that they are hy far the most productive. Ths figures in rsgard to these mines will he found helow.

The Great Gold Belt,

As it is cslled, which lies in the extreme northern portion of the Black Hills, contains the most important mines of this rsgion. Thess minss occupy a spacs of ahout ons and one quartsr miles in length hy half a mile in width. Thsy are grouped into four companies under ons gensral management. These companies are known as the Homestake, the Highland, the Deadwood-Terra and the Father De Smet. The company has just constrncted a railroad to connect their mills with Rapid City. They also own two important canals. Messrs. Haggin, Tevis and George Hearst, all well-known capitalists of this city, are the chief owners of this property, which is nnder the superintendency of one man, Mr. Samuel McMaster. The mines owned hy this company have prodnced within the last five years, up to July 31, 1882,

The Enormous Sum of $10,010,919.

Notwithstanding this enormous total, the per ton yield of the mines has heen exceedingly low, as will he seen hy the following detail:

	Tons Crushed.	Average Yield.
Father De Smet	343,894	$5.79
Homestake	681,733	6 37
Deadwood-Terra	249 329	4.90
Highland	234,081	5.02
Total	1,512,037	average $5.50

There is to he added to the ahove total the amount of $1,694,716 which was taken out of the Deadwood-Terra series previous to consolidatiou, which makes up the full sum of $10,010,919 which these mines have prodnced up to July 31, 1882, and all from rock which averages as yet only $5.50 per ton.

Notwithstanding the comparatively low yield, the following dividends have heen paid:

Father De Smet, 21 dividends	$1,540,000
Homestake, 47 dividends	1,512,500
Deadwood-Terra, 2o dividends	740,000
Deadwood-Terra, before consolidation	350,000
Total dividends	$3,142,500
Total assessments	400,000
Total profits	$2,742,500

Ws havs no records hefors us of the profits of the Highland; hut the fact that its avsrags yield was greater than ths Dsadwood-Terra, which has yielded a profit of $740,000, is sufficient evidsncs that it has hesn a profitahls mine. Ws do not helisve that ths gold mining records of the country can produce auy other instance of so large net rsanlts for the working of such low-grade orss. The showing speaks well of the general managemsnt of ths mine. Ths thres small streams which cut the gold helt in which these mines occur wsre all rich in placsr gnlches helow, hut worthless ahove it. We shall have occasion to speak fnrther in rsgard to the gold found along ths hanks of these strsams, under the head of "Ths Placsr Mines of Dacota," in our next. While at Denver ws mst

Judge H. N. Maguire,

Of the Black Hills Commission to ths Denver Exposition, and from him ohtained many interesting and valnahle facts in regard to the minsral resources and gsneral prospects of the country rspresented hy him, some of which are givsn ahove, hut much mors of which will hs found in our next letter. The Judge has spent the greater portion of his life in the gold and silvsr mining districts of Montana, Colorado, Idaho, Utah and Nsvada, and thsrsfors should he good anthority.

W. B. Ewer.

Refining Gold Containing Copper.

From the author's expsrience, one of the most difficult problems in refining gold hy sulphuric acid is that of treating silvsr and gold alloys which contain much copper, as when ths proportion of the latter metal exceeds 100 per 1,000, fine silver must he addsd in order to hring ths copper down to the required limit, which not only incrsases the weight of alloy to hs dissolved, hut gold dilutes the proportion of gold, so that it is difficult to get it psrfectly fins. The method patentsd hy Roesslsr and Ochsenius for such alloys, is first to convert them into sulphides hy fusion with an sxcess of sulphur, until the silver and coppsr are complstely converted into regulus, and then to hlow air upon the surfacs of the melted regulus. This oxidizes a part of the sulphur with the reduction of an equivalsnt quantity of silver, which carriss down the whols of the gold, giving an alloy, that, when ssparated, is parted hy sulphuric acid in the ordinary way. A certain amount of metallic copper is also liherated at the surfacs hy the rsaction of ths oxide formed upon the sulphids, but this is resnlphuretted on sinking through the hath. By continuing the hlowing in another crucihle after the removal of the auriferous alloy, a cupriferous silver is ohtainsd, which can he easily refined. The air-hlast may hs producsd hy a hlowing oylinder or a steam jet. In ths Frankfort gold refinery ths regulus, in quantities of 300 kilogs., is melted in an air-fnrnace in hlack-lead crucihle, lengthened ahove hy a cylindsr of the sams material, and covsrsd with a projecting shest-iron hood, with a pipe for the admission of ths hlast, which is projected upon the surfscs of the hath. The gases and flue-stuff, formed hy ths oxidation are carrisd hy a lateral opsning in the top cylinder, through a cooling and condsnsing chsmher with nnmerous vsrtical partitions, into an absorhtion vessel, which is filled cithsr with sulphuric acid at 60°, in which sulphats of coppsr is dissolved, or with nitric acid. When a sufficient supply of water vspor is introduced, which is dons hy a steam jet hlower, ths snlphurous acid gas is continuously oxidized and condensed as sulphuric acid of 60°, which is removed from tims to time as it collects. Ths author considsrs that this method may he applied on the large scale to the separation of precious metals from mixed coppsr and lead regulus. In the latter case they will he collected in lsad, lsaving a pure copper regulus. —*By H. Roessler: Berg- und hnttenmanische Zeitung.*

The Roberts Buddle.—The Gsorgetown (Col.) *Courier* says: "Last Saturday we stopped at the Mansfield Co.'s mill, at Dumont, to witness the operation of the Roberts huddle, and are free to confess that we helieve it is the hest slime tahle, without exception, ever invented. This huddle doee not revolve, as is the case with the old style, hut instead the water jets revolve. The stream that carries the slimes ie so weak, that after reaching the tahle it only has force enough to carry off the lightest portion of the tailings, which is washed into a compartment at the outer edge of the tahle and thence to the creek. Thie stream is followed hy a stronger water jet which washes off the remaining tailings, and also takes some ore with them. This product is known as "seconds," and is washed into another compartment, and thence hy slevator is taken up and conveyed to the huddle again for another treatment. A much stronger stream of water follows the second jet and thoroughly cleans the tahle of the remaining ore, which is conveyed to a third compartment and makes the headings, which are an excellent smelting product, and entirely frse from gangue material. It is claimed that hy this process a closer saving can he made with the product of stamps than can he made hy crushing coaree and treating in Hartz jigs."

A new glass, transparent and more hrilliant than common crystal, hut containing no silex, potash, sohs, lime or horax has heen invented hy a chemist in Vienna. It can hs cut and polished, and when fused adheres to iron, hronze and zino.

The California W. & M. Co.'s Dam at Loon Lake—Progress of the Work.

Work on Loon lake dam was suspended for the season on the 19th inst. This dam will now insnre an addition of more than four fest of watsr to ths depth of ths former capac.ty of this immense reservoir, which will he ample to supply all demands during next year. This fact shonld hs a matter of congrstulation to the people of this divide, as nsw and contsmplated mining enterprises will not hs set hack for want of a continuons supply of watsr. The esrly and unprecedented storms of snow and sleet which visitsd this rsgion during the first two weeks of this month created a stampsde among the stockmen and people gsnerally in the higher altitudss, who hastened to the lower hills. A portion of the laborers on ths dam came down, when, Managing Director Findley comprehsnding ths danger which threatsned the nnfinished condition of the dam, and failing to persuade the msn to return, startsd himself the next day for Loon lake in a cold, driving rain. His arrival in camp was hailed with good cheer, and when he told the hoys, rain or snow, coms what may, thoss gaps must he closed, and he had come to help them, all rsspondsd with promptness. For days they worksd in stormy, cold, disagreeahle weather, and at the end of two weeks the gsps were closed, the gats for the trunk mads and put in, and the dam left in good condition. After the first week the wsather faired up, and it has heen fair sver since. It was Mr. Findley's expectation to add three or four more weeks' of work on the dam with ths foros thsy had hefore ths ssason closed, which would have added sseral fest more to ths depth of the reservoir. A good part of ths dam is alrsady huilt to ths requirsd hight, particularly at the trunk and at the wastway. But, as it is, the company may congrstulate thsmselves, for they have mads suhstantial progrsss, and secured ahnndant storags for next year's demands. Mr. Findley and all the forcs, excspt Supt. Wolf and two men, arrivsd hsrs yestsrday. Mr. Findlsy informs us that the company contsmplsts the huilding of a large stone dam on Pilot crsek, near the sits of ths old dam which was washsd out a few ysars ago, and that work may hs hegun next ssason. Ons important advantage in favor of ths security of thsse dams is, that thsy have no rivers to contend against.—*Georgetown (El Dorado) Gazette.*

Aurora's New Mill.

Last wesk, soon after the return of Mr. McIntosh from San Francisco, contrscts wers let to taks down, move snd huild anew ths Silver Hill Mill of Bodie, at Gregory Flat near this hurg. Things have heen systematized, and a nsw order of conditions will soon overtake the dead and sleeping of this district. Several loads of ths huilding and mschinsry are on ths sits, and the rehuilding of ths same commencss next Monday, the 23d inst, and will he pushed to complstion as rapidly as hrains, muscle and coin can do so. George L. Albright has heen smployed to take down the huilding and machinsry and rehuild; Horace Marden ths contract to haul the machinery, and Mr. Barnes, of Bridgeport, the contract to move the huilding. The mill will hs hnilt near ths old Grsgory Mill of halcyon days, and, will he furnished with all modern labor, gold and silver saving improvments, such as self-feeders rock hrsakers sand pumps, etc. The situation is as good as could hs found, there hsing enough watsr in the dryest known season to run a 100 stamp mill; ahundance of the finest nut pine wood, and of sasy communication with the numerous mines of this section. The watsr will he conveyed to ths mill through a 4-inch pips a distance of 3 600 ft., with a square inch pressurs of 100 ft. The numher of stamps will hs 10 (with additional room to add 10 more if demanded) with a sure crushing capacity of 20 tons daily. The mill is heing huilt for the Cortez and Few Emeralda Mining Companies, hut will take all custom ore, guaranteeing a return of 70% of pulp assays. The management mean to be liheral in all dealings with the minere of the district, milling ore at $10 per ton, and granting other privileges seldom ohtained in mining localities. Mr. McIntosh ie deserving much oredit, and has the good will of his fellow townsmen for his resolnte energy, untiring efforts and final success. It will he a cold day now if Aurora is left—all old crones to the contrary—*Esmeralda Herald.*

Going Two Ways at Once.—A mining superintendent at the West says that hy the use of the chronograph he ascertained the fact that the long pump-hohs in his mine moved down at the top hefore they stopped coming nn at the hottom—that is, they went hoth ways at once. This seems absurd, hnt is rational, for the pump-hoh heing 3,500 ft. long, and made of wood, sometime elapses hefore motion at one end is transmitted through to the other. It would he interesting to know exactly where the nentral point is.—*Mechanical Engineer.*

Great Britain prodnced in 1881 55,128 tons of ore, from which 3,000 tons of copper were prodnced. Thie was at the rate of one ton of pure metal for every 14¾ tons of ore. In 1880 they minsd 52,556, and got a rsturn of 3,875 tons of fine copper. This is at the rateof 12⅝ tone of ore to one of fine copper. The great hnlk of this ore comes from Cornwall and Devonshire.

The Engineer.

An English Fourteen-Story House.—During a recent stay in London, says the editor of *La Nature*, we had an opportunity of observing the curious structure shown in the accompanying cut. The building is an apartment house, which, counting the floors beneath the level of the street, and the attics, number 14 stories. Besides these there are two subcellars. This house is located in a new quarter near the Westminster Abbey. On approaching it, the beholder is filled with astonishment at the aspect of a so truly monumental mass, whose total height is about 130 ft. The number of windows in the structure, inclusive of those looking out upon the vast courts within, exceeds 500. The tenants of the house and their visitors reach its different stories by means of a hydraulic elevator, which takes about two minutes to reach the 13th story. After reaching the latter, a marvelous panorama may be observed if the weather is clear. But, as well known, fogs are frequent in London, and it often happens that the tenants of the upper floors are immersed in clouds, after the manner of aeronauts. There is at Genoa an 11 story house, and there have been in former times some constructed at Paris of seven and nine stories, and in the United States numerous experiments have been made with similar structures, these becoming practicable with the use of elevators. The city of London has long had the reputation of having houses only of from two to three stories, but the example here brought to notice shows what can be done by English architects, who, it appears, are not restrained, as they would be at Paris, by administrative regulations.

Dangers of Wooden Structures.—The unsanitary condition of certain towns in this country has drawn attention to the fact that wooden houses and especially wooden foundations are liable after a certain time to cause malarious symptoms. So many malarious attacks have been experienced of late years in San Francisco, that the medical men began to suspect the buildings, especially as the structures themselves, which are nearly all built on wooden foundations, began to show disturbances, cracks appearing in the walls and the floors settling. Scientific investigation into the causes of these troubles points to the fact that the wood used in the foundations became decayed by contact with the sand, which destroys its fibers and leaves it porous and brittle. The next stage in the process is the formation of a fungus growth from the edge of the wood, composed of infinitesimal insect life, which harrows the remaining wood until its vitality is gone, and the insect itself dies. Physicians attribute many of the unpleasant smells and the bad health that hang about the inhabitants of these dwellings to this malarial condition, which to a great extent disappears as soon as proper foundations are substituted for those of wood.

Gunpowder Engine.—A powder engine has been patented in Germany by Herr Beck. In it a piston is forced to and fro in a horizontal cylinder by small quantities of powder ignited on either side alternately. Powder pans are provided on the bottom within, on which, at the proper moment, powder falls through passages from two holders which rest on distribution slides. The igniting of the powder is effected by means of a spirit or gas flame from the cylinder cover, drawn in through an oblique aperture by the suction force of the piston. The access is regulated by slides. The gases of explosion are expelled through holes furnished with slides, on return of the piston. The heavy residues are pushed by the piston into bags, which are emptied at intervals. It is claimed for the new motor that, with small occupied space, it is very effective, and easily set at work. The consumption of powder is comparatively small, and the engine regulates itself. The danger is represented as slight.

Height of Buildings.—In the *Insurance Cyclopedia*, Mr. Walford mentions the Swedish law which came into force in 1875, and which prohibited the erection of buildings in cities and towns of a height more than five feet above the width of the street on which they are built. A wise precaution, says the *American Exchange*, to secure proper ventilation and avert the spread of conflagrations, and which somewhat qualifies Capt. Shaw's rule that the safety or saving of the individual ignited building is indirectly in the ratio of the height to area or cubic content under equal combustible conditions otherwise. This is part of the question, whether we shall in the future build *cities*, or continue, as in the past, to build capacious individual structures.

Proposed Railroad in Marin County.—The San Francisco and San Rafael Railroad Company has incorporated. The company propose to construct a railroad from the junction with the San Francisco and North Pacific Railroad, on Talmalpais avenue, in the town of San Rafael, Marin county, to a point at or near Tiburon Point, on Raccoon Straits, a distance of nine miles. From thence a ferry will be established to this city, a distance of six miles. The capital stock is $500,000. The directors are Peter Donahue, James M. Donahue, Arthur Hughes, T. L. Bergin and Thomas Donahue.

Useful Information.

Artificial Wood.—The latest report of a patented method of making artificial wood comes from Germany, where Herr B. Harrasa has invented and put into practical operation a process which consists of the manipulation of a mass consisting chiefly of cellulose and starch. Common cellulose, sold in the form of paper, is reduced to pulp in water. To this is added, after being drained through a sieve, three parts weight of starch and two parts weight of meal (wheat or maize). The mixture thoroughly mixed is put into tubes of thin metal and boiled over a water bath. When done the allotted time and turned out after cooling the mass resembles glue, which is then mixed with the same quantity of sawdust. This mass is rolled and left to dry in a hot room, and is now ready for use. For pressing into the desired shape iron or steel molds are used heated to 120°, and the mass is subjected to enormous pressure. After cooling the article resembles wood and can be treated in every respect as such, becoming with age bone hard. It can be worked with the saw or file, can be colored, polished, and, when desired, covered with veneer.

New Belting Material.—A machine belting made of woven camel hair, or a hair known as camel hair, is being manufactured and used in cotton mills in Manchester, England. A test of a belt of this material, 6 inches wide and 0.27 thick, showed a breaking strain of 9,181 pounds, with an extension at the rate of 2.68 per cent. at 1,200 pounds, 5 per cent. at 2,400 pounds, 6.60 per cent. at 3,600 pounds, and 13.07 per cent. at 4,800 pounds. It is said that this belt slips less on pulleys, does not deteriorate to anything like the extent of driving belts of vegetable fibre, and is thoroughly waterproof, and not affected by variations in temperature.

Underground Telephone Wires.—Telephoning by underground cables has been pronounced impracticable for the reason that such cables must necessarily each contain a considerable number of conducting wires, and the induction prevents speech. By means of a special arrangement of the circuits, Messrs. Felton and Guilleanme, of Mulheim on the Rhine, claim to have overcome the effects of induction in these cables. Their system was lately tried on a line 32 miles long, and proved so effectual that speech was transmitted without trace of foreign sound through one wire while a neighboring wire of the cable was in constant use.

Alum Water for Extinguishing Fires.—M. I. B. Dumas, member of the French Academy of Sciences, has discovered that water saturated with alum has superior value in extinguishing fires, a value supposed to be due to the coating it gives to objects wet with it, which prevents contact with the oxygen of the air, and thus diminishes the rapidity of the combustion. Experiments are to be made by supplying the firemen of Paris with instruments to throw it, and the Minister of the Interior has recommended that the firemen of the French communes or towns be supplied with facilities to use such solutions of alum.

Fertilizing Moss.—A novelty in horticulture is attracting considerable attention at the flower show of the exhibition of the American Institute. A number of vigorous plants are shown which have for a more or less extended period been kept in a flourishing condition without any earth. The roots of these plants have been simply packed in Dumesnil fertilizing moss, which appears to possess all the elements necessary to their growth. M. Dumesnil's discovery is an interesting one, and many applications, both for floral decoration and for practical horticulture, will suggest themselves.

Incombustible Paper.—The *Moniteur des Produits Chimiques* gives the following recipe for paper which is not destroyed by fire. Asbestos fiber of the best quality is washed in a solution of permanganate of potassa and bleached with sulphurous acid. Ninety-five per cent. of the fiber thus prepared and five per cent. of wood-pulp are mixed in water saturated with glue and borax. A paste is thus obtained which renders the paper fit for the reception of ink. Writing ink which will resist the fire is made of a mixture of chloride of platinum and oil of lavender.

Labor and Material.—A Cincinnati paper tells (perhaps) a big story of a walnut tree. In 1864 an Indiana man, as the story runs, bought the tree for $1, and he subsequently sold it for $65. The buyer sold it to a Cincinnati lumber dealer for $700; the Cincinnati dealer sold it to a New Yorker for $2,200, and he cut it up into veneering, which he sold for $10,000.

To Clean Marble.—Mix one-quarter of a pound of soft-soap with the same of pounded whiting, one ounce of soda and a piece of stone lime the size of a walnut; boil these together for 15 minutes, and then, while hot, rub it over the marble with a piece of flannel, and leave it on for 24 hours; then wash it off with clean water, and polish the marble with a piece of coarse flannel, or what is better, a piece of an old felt hat.

A Metric Guide.—A fact little known is that the United States nickel five-cent piece furnishes a key to metric measures and weights. This coin is two centimetres in diameter, and its weight is five grammes.

The Tractrix Screw Propeller.—A propeller of this type has several points of novelty which deserve attention. Its surface, as its name implies, is generated by the tractrix curve, which is claimed to be the only natural form of least resistance to rotation. The resistance at the root of the screw is abolished, and a direct thrust astern is obtained, the propeller being the only one forming a complete column of water astern at all speeds. The tractrix screw is said to apply its power in the same direction as that in which the water is moving at the time of entering the propeller, and its equal efficiency at all speeds, length and strength of blade, smaller diameter, and the minimum noise when working, are all advantages deserving notice. The propeller appears to be peculiarly well adapted for steam launches, on account of the comparatively small diameter of which it may be made.

A Novel Fire Escape.—The last invention for the protection of theater audiences is a "penetrable safety wall," which has just been patented by an engineer at Kottshus, Germany. The plan is to make the interior walls in all parts of the theater of papier mache, made after a certain method. Such a wall will have the appearance of massive stone, but, by pressure upon certain parts where the words are to be painted in luminous letters, "To be broken open in case of fire," access to the exterior corridors is to be obtained, whence escape to the outer air can be made.

Teeth Factories.—There are at present in the United States 12 large factories for the production of artificial teeth, turning out between them 10,000,000 teeth a year. The gold used in stopping decayed teeth in America amounts to $2,500,000 yearly.

Glycerine in Glue.—Herr. Puscher, a German chemist, has reported that the value of glue is greatly increased by the addition of 25% of glycerine, all cleaving and breaking of the glue being thus prevented.

A horse-shoe invented by William G. Howell, Philadelphia, Pa., consists of a center of steel wholly inclosed in iron, to which it is welded, and is provided with a steel wearing edge running through the calks of said shoe.

Good Health.

The Ear Drum Ruptured by Diving.

Dr. H. A. Wilson, aural surgeon to St. Mary's Hospital, Philadelphia, reports two cases of rupture of the drum of the ear, caused by diving. In both cases the hearing was seriously impaired, but the wound healed in the course of 10 or 15 days. Dr. Wilson says:

The mechanism of the rupture is not difficult of explanation. The water, forcibly impinging upon the column of air in the external auditory meatus, suddenly increased its pressure upon the membrane, while the normal pressure upon the inside remained unchanged. The eustachian tube permitted the the air to escape from the middle ear, and thus it will be seen that there was no resistance given to the internal column of air. The internal force of resistance being suddenly exceeded by the external impinging force, the rupture ensued. To prevent rupture when diving it is necessary that the pressure upon the membrane from without should be compensated for by an equal resisting pressure from within. To accomplish this, a full inspiration should be taken prior to diving; the mouth kept shut, and, to prevent the escape of air by the nose, the posterior naves should be closed by elevating the soft palate. This is done almost involuntarily, and retains the inhaled air in the lungs, buccal and aural cavities, its compression being produced by the contractions of the chest and cheek muscles. The act of swallowing will force sufficient air through the eustachian tube into the middle ear to resist the pressure from without.

Holding the nose is not essential to the closure above referred to, but is a crude method of accomplishing the same result, and is resorted to by those who either have not sufficient control over the palatine muscles, or who do so through fear of swallowing the water.

Bathers should be careful to guard against accidents of this nature, which Dr. Wilson believes to be more common than is suspected.

After a rupture of the drum-head, if the parts do not unite, there will be left a permanent opening, and the inconvenience caused by air whistling through it is not the only thing to be dreaded. The delicate structure of the middle ear being directly exposed to the action and changes of the atmosphere, serious inflammatory changes are apt to take place, and purulent discharges and impairment of hearing result.

The eye being exquisitely sensitive to the slightest touch, takes cognizance of the presence of the most minute irritant, and prompts the patient to seek immediate relief. The absence of this sensibility in the ear is very frequently the cause of neglect to attend to it when injuries of this organ take place.

Offensive Breath.—This is generally an annoyance to the person who has it, and is especially annoying and disgusting to his friends. Sometimes it is caused by decaying teeth. If so, it is unwholesome, for the person who has it inhales with every breath putrid particles that are absorbing into his blood. A good dentist should be seen, and if the offensive odor is caused by decaying teeth, he can soon "abate the nuisance." But quite often bad breath is caused by the blood's being loaded with waste matter, which ought to have been separated—eliminated—from it by the liver and other glands. Waste in the body must be gotten rid of somehow, as certainly as the waste of our dwellings must be taken away, if we would have them healthy. Nature has provided glands whose office is just this, and whose powers, in health, are fully equal to it. In case these fail somewhat of their work—if they failed in full, speedy death would result—it is done in part by other glands, which are then said to act vicariously. Thus, the skin can come to the relief of sluggish kidneys. The kidneys, in turn, can aid the skin when its pores are closed by a cold or a fever. So, also, matter which should be separated from the blood by that great gland, the liver, and by other intestinal glands, is taken from it by the mucous glands of the mouth and air-passages. In the process, however, it is more or less changed chemically, and gives the breath its disagreeable odor. To correct this disorder it is necessary to arouse the proper glands to a higher activity. The stimulus should be slight and continued for some time. As all the excretory organs aid each other, it is well to stimulate the skin and kidneys, also, for a short time at least. As the trouble in the first place often brings with overeating, the diet should be diminished and regulated.—*Ex.*

The Important Period of Man's Life.—From the age of 40 to that of 60, a man who properly regulates himself may be considered in the prime of life. His mature strength of constitution renders him almost impervious to the highest attacks of disease, and all the functions are in order. Having gone a year or two past 60, however, he arrives at the critical period of existence. The river of death flows before him, and he remains at a standstill. But at what this river is a viaduct, called the "Turn of Life," which, if turned in safety, leads to the valley of "Old Age," around which the river winds, and then flows without a doubt of causeway to effect its passage. The bridge is, however, constructed of fragile materials, and it depends on how it is trodden whether it bend or break. Gout, apoplexy and other bad maladies are also in the vicinity to waylay the traveler and thrust him from the pass; but let him gird up his loins and provide himself with perfect composure. To quote a metaphor, the "turn of life" has a turn either to a prolonged walk or into the grave. The system and power having reached their utmost expansion, now begin either to close, like the flowers at sunset, or break down at once. One injudicious stimulant, a single fatal excitement, may force it beyond its strength, whilst a careful supply of props and the withdrawal of all that tends to force a plant will sustain it in its beauty and vigor until night has nearly set in.—*Herald of Health.*

A Curious Disease.—It has been observed that the manufacture of bichromate of potash has a singular effect upon the nose, manifesting itself in a curious manner. A little hole is formed on the septum or partition of the nose dividing the nostrils, and increases gradually until the partition entirely disappears, with the exception of its lower part, so that to a superficial observer there is nothing the matter with the nose, except a little outward depression. As soon as the partition is destroyed the process appears to stop there, neither the lungs, air tubes nor throat being in the least degree affected. Some workmen at the chrome factory in Russia, where the disease has been chiefly watched, have been employed for ten years and remained unaffected, while with others the hole in the nose begins to be formed after one month's work. But that the disease is something more than an individual peculiarity is evident from the fact that an inspection of all the hands proved that more than 50% of the men had diseased noses. The early symptoms are a slight tickling of the part affected, followed by bleeding, but with no uncomfortable feelings, and, in fact, the destructive process is painless.

Bow Legs.—In most cases, bowed legs are the consequence of a child having been urged or permitted to attempt to walk before the bones had become sufficiently developed and firm to bear the weight of the body. There are too many cases of this kind; we meet them nearly every day. The way a child lies in the cradle, on the side, with the legs drawn up, is also said to be conducive to bowleggedness. For their possible correction prompt consultation should be had with some competent surgeon. Apparatus may be devised which will exert a steady pressure on the limb and in time reduce the bone to shape approaching the normal.

Eating Sand for Dyspepsia.—A new and simple cure for dyspepsia was brought to my attention by Hon. Pope Barrow yesterday. He says: "You know Webb Barber in Athens. Well, sir, he has cured himself of dyspepsia by eating white sand. Just common white sand picked up in the bed of a branch. He says that chickens eat sand to digest their food with, and he didn't see why men might not do the same thing with profit. He ate a dose of sand every day and it cured him. Judge Henderson, the Commissioner of Agriculture, told me last night, he was eating sand for dyspepsia with good results."—*Ex.*

Passing Events.

The snows have fallen in so many places that prospecting has been suspended nearly all over the higher regions. But there remain areas large enough where the winter is so mild that men can work until the sun travels north again. The mountains of New Mexico and Arizona and the southern part of this State are good places to prospect in the winter. We give on another page of this number of the PRESS a map and description of a new region in New Mexico that is now attracting great attention from miners and prospectors.

Of course the principal topic for the past week has been that of election, and now that the results are known, the public still talk on the subject, to the exclusion of other things of interest.

Local news from the mines is somewhat meager just now, but from wherever we hear work appears to be going on with generally favorable results. It is pretty likely that the bullion product of the year will be fully up to the standard of past years.

A NEW ALLOY called "argasoid," recently described by Mr. V. Jeuptner, of Vienna, has been used as a substitute for silver. Its cost is said to be about 50 % more than brass. Its chemical composition is as follows: Tin, 4 035; lead, 3.544; copper, 55.780; nickel, 13.506; zinc, 23.198; iron, trace.

Cause of Mining Accidents.

In European countries the governments legislate on the questione connected with the safety of those who work in mines. The special regulations looking to the safety of the miners are strictly enforced. This is particularly the case in France, yet even under the most careful managements many accidents occur. Take France, for instance; the number of accidents is large, nearly two per cent. of the men being killed or wounded each year. In one year, lately, 2.06 men per 1000 employed in mining were reported as killed, and 17.73 per 1000 as wounded. The coal mining interests of France so greatly exceed the rest that one might suppose the accidents ascribable to the peculiar dangers met in the extraction of coal. Such, however, does not seem to be the case. The injuries arising from the explosion of fire damp and asphyxia amount in only eight in 10,000 coal miners. A majority of the accidents, especially of the fatal ones, in all classes of mines, are caused by the caving in of ground.

And yet this is a form of accident which may be said to be more under the control of the miners themselves than any other. Caving is nearly always due to defective or careless timbering. When the nature of the ground is known, due precaution can always be taken. The men themselves, working as they do right on the spot, and placing the timbers, can always judge better than any one. But they become careless, and to save trouble let things go half done, that, so left, endanger their lives.

The men themselves are largely to blame in the great proportion of accidents. We all know that experience has proven that men in fiery coal mines are not to be trusted to protect their own lives. Lamps have to be locked, and the men searched and matches taken from them, to prevent their smoking, where an open flame from a match may kill the man himself and hundreds of others with him.

With every safeguard thrown around them for their protection, working miners will be more or less careless. Eight out of ten of the accidents in blasting are due to the men doing things they are expressly warned not to do. Men will thaw Giant powder cartridges in an oven, will pick out old charges, use poor fuse, stand near a blast, and do a dozen other things they are told not to do. If the high explosives are judiciously handled and directions explicitly followed, there is no danger in their use. But the carelessness of the men causes many accidents that are laid to the powder. In fact, the larger proportion of our mining accidents seem to be from causes more or less directly connected with the use of blasting compounds.

There are so many safety appliances connected with the cages and hoisting apparatus that accidents in that direction are not so frequent as formerly. At one time it was a common thing for the cage to be hoisted into the sheaves, and hundreds of men have been killed that way, but the accident is by no means common. Men still continue to fall down shafts, and the number who do this can always be predicted each year, though it is nearly always the result of carelessness.

Our Government, unlike those in European countries, exercises no control whatever over these matters. In some of the States laws have been passed compelling owners to have more than one shaft to mines of the specific depth in order to ensure the escape of the men in case of fire in the main shaft. But there are no Government or State inspectors to see that measures for the safety of the miners are carried out. The miners always have the remedy of the courts for damages if there is culpable carelessness or disregard of ordinary precautions on the part of the owners of the mines.

It is evident, however, to any one who has given the subject any attention, that in most cases accidents are due to the thoughtlessness or over confidence of the working miners who, from the constant presence of danger, come to disregard or ignore it. If they would always exercise discretion and prudence, the number of mining accidents each year would be materially reduced.

THIS year's output of the Wood River and Sawtooth mines in Idaho is estimated at $3,000,000, which is double the amount produced in the whole Territory of Idaho in 1879. It is said that over $1,000,000 has been invested in Wood River mines in the past year. There is an impression that Idaho will open up a large bullion product in the next five years. What is wanted is railroads to make that section of the country a promising field for the honest miner.

THE *Calico Print* gets it from one of the owners of the Oriental mines, that within a week or two work would be commenced and the machinery shipped for the mill as soon as the foundation could be laid. The mill is to be situated within a half mile of Calico Station. As all other mills will be built there, a narrow-gauge railroad is to be built from that point to Calico.

GENERAL HARNENBERG, who has been in Nevada county obtaining statistics for the forthcoming report of the United States Mint Director, says the *Transcript*, thinks returns will show that the mines, notwithstanding the injury wrought by anti-debris litigation, are now producing much larger sums than for several years past.

Rainfall and Mines.

The importance of the rainfall to the mining interests, particularly where gold is the metal sought for, is well known to all mining men. Without water, and an abundance of it, surface mining for gold cannot be profitably carried on; and to no one, not even the farmer, is an abundance of water more welcome than to the miner. He can utilize every drop that comes to him, for, as a general thing, the more water the more gold. Thus, in a placer-mining country, there is a direct ratio between bullion product and rainfall.

In dry and arid regions gold mining is seldom profitable. The ground must be very rich indeed to pay well with a scant supply of water. There are gold placers in many places in Mexico and in South America, and in the southern parts of this coast, that would pay well if they were in a region where water could be brought to them. Even in California, old miners will tell you of places it would pay to mine if they could get water there. In South America placers are worked that only have water a month in a year, and in several localities are large deposits of auriferous material that cannot be mined at all for lack of water.

No method of working auriferous ground by a dry process has ever proved to be profitable when done on a scale of any magnitude. In fact "dry washers" as they are called must have rich ground to be worked favorably, and the gold itself must be in a condition as to specific gravity compared with the ground, such as will admit of the machine separating it. Very fine or scaly gold is not saved by these machines, but "shot gold" or little nuggets are caught.

In California the placer mines are on the wet side of the great range of the Sierra Nevada, which serves as a sort of reservoir for a large fall of rain and melted snow. The miners have aided nature and made immense reservoirs by damming up the outlets of canyons or small valleys and making lakes. They also bring by pipes to these lakes or reservoirs all the available water from small streams and springs, thus keeping the water back until it can be used to advantage.

Although the mountains receive a large amount of rain and snow, unless the precautions referred to were taken, the mining season with us would be short. The hydraulic process of mining takes an enormous quantity of water, and our rainfall would be insufficient to supply this were it not carefully stored. In Australia the comparatively small range of mountains and the distribution of deposits is against the miner, who is often compelled to contend with lack of water. On that coast the yearly rains amount to, say, from 20 to 50 inches. The quantity diminishes toward the interior, and on the western slope of the Cordillera some places escape rain altogether. Here with us the mining regions are fortunately in the regions of good rains. Any one looking at a table of annual rainfall, will find that the gold production varies as with the amount of rain.

A BOILER exploded at the Betty O'Neil mine hoisting works, Lewis district, Nev., on Tuesday of last week, instantly killing T. G. Bastian, cage tender, and fatally injuring a Chinaman who was firing. Judge D. C. McKenney, G. W. Bateman, engineer; D. P. Pierce, superintendent; R. Hazlett, ore sorter; August Bell and Steve Bordell had a most miraculous escape. Judge McKenney and G. W. Bateman were near the hoisting engine, and only escaped being crushed to death by a water tank, which held portions of the building above them. One half of the boiler was blown within eight feet of them. The works are a total wreck, the gallows frame being the only thing left standing. Pieces of the boiler were carried several hundred feet, and lumber and pieces of iron pipe are scattered over the adjoining hillside.

TO BE REBUILT.—Mr. Read, Supt. of the Eureka Con., tells the *Sentinel* that the exploded accumulator at the Locan shaft will be replaced without delay by another of much greater strength. The material used will be of the best quality, and the moldings will be tested to such a degree of resistance that no fear will be felt of a recurrence of the recent catastrophe. The new accumulator will have to be built from the base up, and will be of greater dimensions than the first. Work will be resumed at once to repair the damage done to the building.

U. S. GEOLOGIST, J. C. RUSSELL, and party are at present in the Mono Lake country, making Government observations. Mr. Russell is now camped on Lee Vining creek, but will in a few days move to Silver Lake, where he will take observations, and then return to Mono Lake, and, it is presumed, will sound its depth and make other important examinations of that water and its vicinity in, at the farthest, two weeks.

RETURNING Wood River prospectors report that hard times are sure to come upon many they left behind in the blustering country. Prospecting is entirely suspended for the season.

THE North Bloomfield Hydraulic Mining Co. gives employment to every steady man who applies for work.

Electricity versus Gas.

Notwithstanding the rapid strides which electricity is making both in the direction of power and for illuminating purposes, there is no doubt but that gas still continues to be an institution of the utmost importance. When the monopolies in that manufacture are effectually broken up—as they will be by the more general introduction of electricity—both the rich and the poor will largely resort to gas as a heating agent. Experience has abundantly shown that it may be conducted to great distances, as from collieries, a matter which will largely tend to cheapen its cost.

The slow progress made in its application for heating purposes is largely due to the objectionable practice of reducing the pressure in the mains during the day-time to the lowest possible point consistent with the prevention of atmospheric indraught. The introduction of the electric light has convinced gas managers that such a policy, as well as that of needlessly large profits, is no longer tenable, but must give way to a policy more conformable to the technical progress of the day.

Gas Engines.

Gas also presents some most important advantages in the production of heat for mechanical effect. Reliable engineers inform us that the best expansive steam engines yield only two-sevenths part of the heat communicated to the boiler from coal. From this small amount of return we must also deduct imperfect combustion, heat carried away by the chimney, and a largely increased loss by friction and reduction of the steam over the gas engine. This real effect produced by coal as applied to the steam engine, is thus reduced to about one-seventh its theoretical value; while the factor of efficiency of the gas engine, even upon such high authority as Dr. C. W. Seimens, reaches fully one-fourth.

Dr. Seimens, in his late address before the British Association, said: "The gas or caloric engine combines the conditions most favorable to the attainment of maximum results, and it may reasonably be supposed that the difficulties still in the way of their application on a large scale will gradually be removed. Before many years have elapsed," continues the Doctor, "we shall find in our factories and on board our ships engines with a fuel consumption not exceeding one pound of coal per effective horse power per hour, in which the gas-producer takes the place of the somewhat complex and dangerous steam boiler."

Hence it may reasonably be inferred that gas and electricity will go together, hand in hand, as useful and efficient servants of the people for centuries to come. Each will have its appropriate work to do, and each will in time drop quietly into its own appropriate sphere of usefulness and efficiency.

Trouvelot's Astronomical Drawings.

It is seldom that our attention has been called to a publication of greater interest or value than the series of astronomical drawings recently published by Charles Scribner & Sons, of New York. These drawings (15 in number) are printed in the highest style of the lithographic art, upon fine cardboard sheets, some 2½ by 3½ ft. in size. They consist of: "A Group of Sun Spots and Veiled Spots," "Solar Protuberances," "A Total Eclipse of the Sun," "Aurora Borealis," "The Zodiacal Light," "Mare Humorum," "The Planets Jupiter and Saturn," "The Great Comet of 1881," "The Great Nebula in Orion," etc.

The drawings were prepared by E. L. Trouvelot while a member of the Observatory of Harvard Observatory. No more fitting man could have been secured for the work, which represents to the general student and to the public, with the utmost possible accuracy, minuteness and beauty, the chief celestial objects and phenomena, as near as art can do, just as they appear in fine telescopic detail. They are represented not only in general appearance, but even the peculiar and delicate colorings as they appear to the trained eye of the astronomer are reproduced with most vivid effect.

The work is one of such dignity and importance as to need nothing but its own merit to recommend it to the attention of every student and to all who take any interest whatever in celestial phenomena, and as a feature in private libraries it will be a valuable means both of gratifying and begetting a taste for astronomical study. These drawings should find a place in every grammar and high school in the land. Their beauty, accuracy and size make them invaluable upon the walls of a classroom. The chief astronomers of the world have already expressed personally and officially their appreciation of the value and accuracy of these charts, and portions of the series have been awarded by the French Academy of Science with the Volz prize and a gold medal.

These magnificent drawings have been employed among other attractions to fit up a scientific booth at the Authors' Carnival in this city, where they have attracted a large share of attention from the immense audiences which assembled there from evening to evening. They may be obtained of Mr. E. S. Parker, special agent, 420 Bush st., this city.

Progress in Electric Engineering.

The announcement has been made that Adolph Sutro has purchased a controlling interest in the Omnibus street railroad of this city, and proposes to introduce many improvements in the management of the road, the chief of which will be the substitution of an electric motor in place of horses, and in preference to steam. The road will also be extended up Tenth, and from thence out to the Park. It is proposed to use electricity by storage, the accumulators being charged at some convenient central point. The machinery will be simply a lever, connecting with a box in which the electricity is stored, the whole apparatus being situated in the front platform. Pushing the lever starts the car; reversing it makes a stoppage. A belt connects the engine with the car wheels. The boxes in which the motive power is stored are, say, 10 inches in dimensions. Each one has a force of three-horse power. They will be placed under the seats in the car, and out of sight, if this scheme is adopted. The system is what is known as the Sellon & Volckmar accumulators, a modification of the well-known plan of Plante of Paris.

Paris now has a road run by such machinery. The Berlin electric passenger road was examined by Mr. Sutro. He says it is simply a wire cable stretched above ground and on poles. The electricity is stored in the rails. It could not be so used here, because horses' traveling between the rails, and making a connection by treading with their iron-shod hoofs on them, would be stunned by the resulting shock. The only practicable application of the principle here, is the use of either the electrical accumulators or an underground cable. He favors the former. A saving of nearly $6,000 per month would be made by doing away with horse-flesh and stable hands. It might be a still further improvement if the cars should be lighted by electricity, as has been done for the last 10 months by the London & Brighton railway of England. The value and the eventual introduction of electric motors, in certain specialities, can no longer be considered a matter of doubt.

Electric Lighting.

Still another important matter in regard to the progress which electricity is making in this city, is the announcement of the formation of an Edison Electric Light Company, to do a general illuminating and power business. Capital stock, $5,000,000, of which $3,500,000 was taken before the public announcement was made. It is the intention of the company to establish a large electric lighting district as soon as the necessary machinery for such a purpose can be constructed. Mr. Ladd, the principal stockholder and promoter of the enterprise, declares that the success and economy of the Edison lighting district in New York has exceeded that inventor's expectations, notwithstanding the studious circulation of reports to the contrary.

No reasonable doubt can now be entertained that electricity will eventually occupy an important position as a public luminant. Even though its cost should be found greater than gas, it will be preferred for the lighting of drawing, assembly, and dining rooms, museums, warehouses, factories, mines, etc. Assuming the cost of the electric light to be practically the same as gas, the preference for one or the other will generally be decided upon grounds of relative convenience. The people are fast becoming familiar with the character of the light, and although at first its greater intensity and brilliant whiteness produces somewhat painful and unpleasant sensations, that feeling is gradually wearing away. Improvements are also being rapidly introduced tending to cheapen its production, control its intensity and measure its quantity—the latter with even more precision than in gas, so that buyers will be required to pay only for what they actually need and use.

A Rough Prospecting Trip.—The San Bernardino *Index* says: One of the most marvelous trips ever made is that recorded by Hank Brown, who has just returned from the Desert in company with three other men, two named Vines, and a man named Hunter. They started for a prospecting trip with a resolve to make or break, and it has resulted with considerable of both. During the trip Hank Brown walked a distance of 320 miles. All of them were compelled to walk over 200 miles. Three of their horses died from thirst, and they had to abandon wagon and provisions. With nothing but their guns they wandered from Providence Mountain down to Toros, their only food being what few birds and animals were killed along the route. At one time Hank says they had a huge stew of rabbit, quail, terrapin, squirrel, hawks and blackbirds. The heat was almost insufferable, and the hardships of the journey were enough to kill ordinary men. The party made several rich mineral discoveries, and feel well repaid for the trip.

The Cerro Gordo Mining Co., of Lake Valley district, New Mexico, paid its first dividend at Philadelphia on the 1st inst. The amount was 25 cents per share, or $100,000.

There are still lots of tailings in the Raymond & Ely pits, notwithstanding the great amount put through the furnaces.

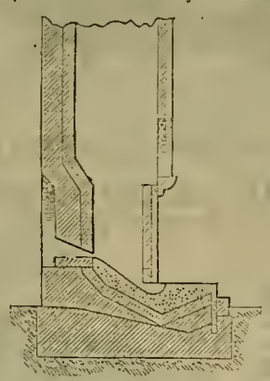
The Great Republic mine in the Clark's Fork country, M. T., has been sold for $60,000.

Reduction of Litharge.

The reduction of lead from the oxidized products produced during the cupellation of lead, as litharge, *abstrick abzugs*, and also from the dross obtained from the Pattinson pots, skimmings from the softening of hard lead, etc., is affected either in reverberatory or in blast furnaces, but in either case using carbonaceous matters as charcoal or coal—as the reducing agent.

In England and France, at Nassau, Tarnowitz, and other places on the continent, a reverberatory furnace is employed, in which the bed slopes from all parts towards a tap-hole situated either at one side of the furnace or at one end, and from which, in either case, the metal collected at the lowest part of the hearth overflows a kind of dam formed in the tap-hole, and passes into a cast-iron pot placed outside the furnace, from which it is ladled at intervals into ingot moulds; while at the close of the shift or day's work, this dam is broken down, and the separated lead collected on the hearth is tapped out into the lead pot before mentioned.

For treatment in the reverberatory furnace it is not desirable to reduce the litharge to a state of fine powder—the decomposition succeeding best when the particles of litharge and fuel are in the form of small pieces which lie loosely upon the hearth; and it is further necessary that the contact of the litharge with the furnace bottom be prevented as effectually as possible, for which purpose there is first introduced on to the red-hot bed of the furnace a depth of from two to three inches of small coal, which undergoes a process of coking during the time that the charge of litharge, mixed with sufficient coal slack to effect its reduction, is being introduced into the furnace and spread evenly over the bed of coal first introduced. From five to six cwt. of the smelting mixture is then introduced into the furnace at once, and the temperature is maintained just sufficient to



Vertical Section of Litharge Furnace.

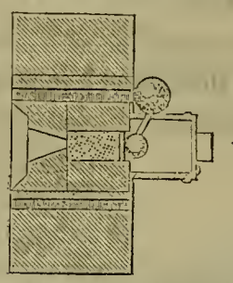
melt the charge, when the litharge suffers reduction, and in from one and a half to two hours lead begins to flow over the dam into the lead pot. The reaction continues to the end of the shift, fresh additions of litharge and coal being made at intervals to continue the supply of lead; while the residue remaining on the hearth after the lead ceases to flow, and which contains the ash of the fuel, along with unconsumed fuel and some unreduced litharge, is then well rabbled at intervals; and the temperature is raised so as to induce a state of semi-fusion in the mass, with the separation of a further small proportion of metallic lead, after which the residue, constituting "litharge slag," is drawn out from the furnace. This product (litharge slag) still retains some undecomposed litharge, and probably also shots of metal; and for the more complete extraction of the metal therefrom, it is subsequently treated in a cupola furnace or in the slag hearth.

Instead of the reverberating furnace above described it is the practice at Freiberg in Saxony, in Silesia, the Hartz, etc., to effect the reduction of litharge in low cupola or blast furnaces, as shown in engraving, which were formerly but some eight feet in hight, but are now built somewhat higher ranging from 15 to 20 ft. from the twyer to the mouth. The hearth is made of a brasque of clay and charcoal or coke well rammed in, and the reduced metal which collects in the hearth passes beneath the fore-wall to the fore-hearth, flowing from thence along a gutter or channel into the receiving pot into which the lead and slags are tapped at intervals as required; while the charge is introduced through the opening above the fore-wall. Either charcoal or coke is employed as the fuel in these furnaces, and the blast is supplied through one twyer with a Ω shaped nozzle worked with a small slag prolongation or nose. The materials of the charge consist of litharge broken into lumps together with about 15% of fuel; and if the litharge be impure or mixed with marl, etc., from the substance of the cupel, a small proportion of litharge slags is also introduced into the furnace, the litharge being thrown against the forewall and the slags with the fuel towards the back whereby the lead which is reduced from its oxide by charcoal at a moderate heat, trickles down towards the hearth where it collects. The above distribution of the charge facilitates its descent to the hearth with a minimum duration of contact between the blast and the reduced lead, since prolonged contact of the two would be attended with the re-oxidation of the metal. The slags which should be tough are usually rich in lead, containing from 20 to 30% of the latter, and are accordingly treated in another blast-furnace or slag-hearth for the extraction of a further preparation of their lead. The amount of litharge that can be passed through one of these furnaces depends much upon its purity—the greater the proportion of foreign matters that it contains, the smaller is the quantity smelted during the day of 24 hours, but the purer varieties, such as that obtained from the direct cupellation of ore-furnace lead, about 90 parts of lead are extracted from 100 of litharge treated.

A New Medical College.

The Cooper Medical College was formally opened in this city last week. The handsome building is a generous gift of Dr. L. C. Lane, of this city. The college is named after Dr. Elias Samuel Cooper, who died in this city some years since. The faculty of the new college, composed of Doctors Lane, Gibbons, Ellinwood, Barkan, Mythe, Gibbons, Douglass, Hirshfelder, Cushing, Johnson, Door, Plummer and Farnum. The building is constructed from a study of designs of the leading medical colleges of the United States. The plans of the Rush Medical College, Chicago, were obtained at considerable expense, as were also the plans of some medical buildings recently built in England. As these plans were in some respects improved upon, the Cooper Medical College is believed to be the most perfectly appointed and arranged building of its kind in the United States. The cost of the building, added to what Dr. Lane was offered for the ground, makes a total of over $100,000.

The existence of the Cooper College is due to the professional earnings of Dr. Lane alone, who, as an evidence of his love for the memory of his late uncle, Dr. Cooper, gives his name to the new college. The details of the arrangement of the new college are as follows: The ground plan is for a structure 80 ft. by 90, and five stories high. It is of brick faced with



Horizontal Section Through Tuyere of Litharge Furnace.

pressed brick, and trimmed in stone at the openings for windows and doors. Internally, the building may be described as follows: The basement has its store-rooms and heating apparatus. On the ground floor are the waiting-rooms, the apartments for consultation and for chemical instruction. On the second story are two large class-rooms, each 30x30, and an assembly-room or hall for lectures, 66x40. The third story has a large chemical laboratory and lecture-room; the fourth a library, museum and reading-room; the fifth is arranged for a laboratory, microscopical and anatomical researches.

Wood River Bullion.—It is of course impossible, as yet, to state with any degree of certainty what the yield of the Wood River mines will be this year, as the shipping season will will not close for at least six weeks. But sufficient is known to warrant the statement that it will be nearly, if not quite, double that of last year. The hullion mines will ship much more than last year, and the aggregate from that camp alone may not fall short of $1,000,000. The following figures may be accepted as a reasonable estimate of the value of the shipment from the mines of that camp: The Mayflower, $250 000; Idahoan, $150,000; Jay Gould, $150,000; Bullion, $100 000; O. K., $50,000; other mines, $100,000. The yield would have been twice as large if transportation could have been secured. The dumps are buried in ore sacked and ready for shipment, but not a team is to be had.—*Times.*

Dental College.—The commencement exercises of the Dental Department of the University of California were held in B'nai B'rith Hall, Wednesday evening. The valedictory on behalf of the faculty was delivered by Prof. S. W. Dennis, M. D, D. D. S., and on behalf of the class by H. T. Piomteaux. President W. T. Reid, of the University, conferred degrees upon graduates of the session of 1882. Addresses were delivered by Governor Perkins and Rev. Horatio Stebbins.

The Con. Virginia and California Mining Cos. paid $13 000 in paying off the men the other day. The Utah mine wages were $4,000. The pay roll of the Union was $12,551.

Carbonic Acid Gas in Mines.

Too much care cannot be exercised to guard against carbonic acid gas in mines. It not only exists in large quantities in a natural state, but is constantly being formed by the exhalations from the lungs of the men and animals, the products of combustion in the miners' lights, the ventilating furnaces, and especially the small locomotive engines now so much employed. When mixed with common air it is only safe up to the proportion of five per cent., though it is said that some miners become so accustomed to it that they can breathe an atmosphere charged with 20 per cent. of carbonic acid. Mr. Andrew Roy, State Mine Inspector of Ohio (Third Annual Report, 1876), calls attention to the insidious workings of this unseen but deadly foe of the miner. "The air," he says, in speaking of the comparatively shallow mines of Ohio, where natural ventilation is depended on to a very great degree, "is best in the morning, because the circulation is partially, if not wholly, renewed in the night, during the absence of the miners; but in the afternoon and toward quitting-time it becomes very foul, and miners frequently leave work because their lights will no longer burn, or because they are so oppressed with languor and headache that they can no longer stay in the mine. The black-damp, however, is more insidious than direct in its operations, gradually undermining the constitution and killing the men by inches. By reason of constant habit, young and robust miners are able to stay several hours in a mine after a light goes out for want of fresh air, where a stranger, unused to such scenes, would fall insensible, and, if not speedily removed, would die."

Similarly, Mr. J. K. Blackwell, appointed British Commissioner of the Mines in 1849, with instructions to make an inspection of their sanitary condition, reports: "There is another class of injuries, resulting from defective ventilation, to which miners are exposed. The circumstances producing these injuries are slow in operation, and as their effects bring disease, and not immediate and sudden death, their existence has been little considered. These effects are the result of an inadequate supply of air, which has become vitiated and unfit for breathing, on account of its having lost its due proportion of oxygen, which is replaced by the formation of carbonic acid.

"This gas has its sources in respiration, the lights of the mine, the decomposition of small coal in the goaves (cavities of the roof), and of timber in the workings. Air in this state is also usually found to be loaded with carburetted hydrogen, yielded from the coal or in the goaves. Sulphuretted hydrogen, arising from the decomposition of pyrites, is sometimes present, especially in coal seams liable to spontaneous ignition. The gases formed by blasting are also allowed to load the air of mines to a very injurious degree."

And Thomas F. Foster, Government Inspector in 1864, says: "In collieries that I alluded to as being badly ventilated, they had no inflammable gas, and that was the reason why they were not well ventilated. Although you sometimes kill a few men by an explosion, these collieries where they have no inflammable gas kill the men by inches. There are quite as many, in my opinion, killed where there is nothing but carbonic acid gas, as where there is inflammable gas. The men's health is naturally destroyed, and they kill them by inches. They do not go immediately, but they go in for a few years and die." Attention is called to Mr. Foster's remarks. Colliery managers are altogether too prone to think that fire-damp is the only damp that is to be feared, and force their men to work year after year in an atmosphere loaded with carbonic acid, because in this gas they die slowly and one by one, dropping off without any of the dramatic circumstances attending death by an explosion. It is cause for congratulation that the improved state of science, and the requirements of the mining laws in all civilized countries, have greatly improved the condition of the mines with regard to ventilation.

Harney Valley.—The Malheur Indian reservation for the Piutes of this State, but which the Pintes repudiated, having now been declared public lands by the Government, and thrown open to settlement, that particular section is experiencing quite a boom. A correspondent of the Grant county *News* says there are two busy, bustling little towns in Harney about a mile apart, each vieing with the other as to which shall get the "bulge" and become the future great city of the as yet undeveloped region. Each has a store, hotel, saloon, blacksmith shop and race track. One has a post office, and is called Egan, after the Piute chief who was so treacherously slain by the Umatillas in 1878. The other goes by the temporary name of "Stony Point," and several other aliases at present, the inhabitants being unable to decide which of the many names suggested as being high-sounding enough for a large city to adopt.—*Virginia Enterprise.*

Owing to the parting of the long and crooked smokestack running through the upper drifts of the Day mine (Nevada), last week, the mine was filled with smoke, and work was suspended for a couple of days, permitting the smoke to get out of the mine.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description.

WAREROOMS: 92 & 94 Liberty St., New York,

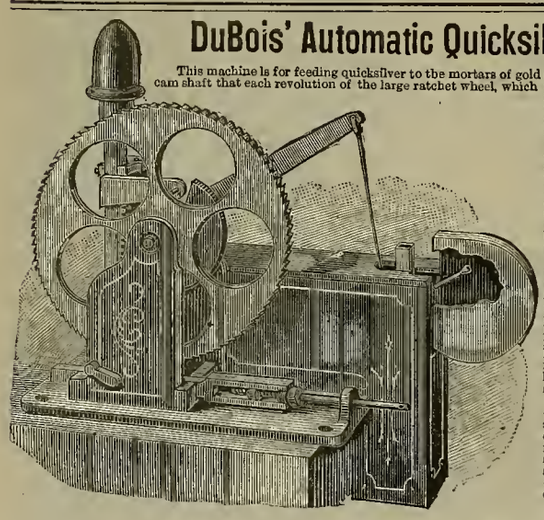
Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of **Morey & Sperry** are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of **Morey & Sperry**, will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-Class.

MOREY & SPERRY MINING MACHINE CO.

DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.

The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.

A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; i. e., from every one to four minutes.

Price, complete, $75.

For Sale by **WHITNEY & MARSHALL,** Sole Agents

22 & 24 Fremont St., San Francisco.

Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

THE RAPID ORE CONCENTRATOR.

Patented March 28, 1882, by G. A. METCALF, of Malden, Mass.

CHEAPEST AND BEST **CONCENTRATOR** In the Market.

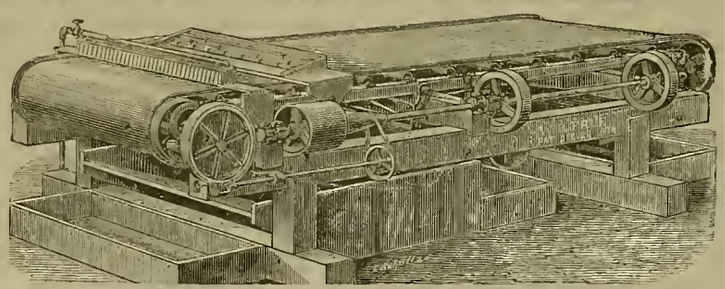
$1,000 CHALLENCE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Savee from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horee power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make teste, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

New Mexican Mines.

(CONTINUED FROM PAGE 305.)

east slope of the hill, where a small space of a few hundred feet has been mined to a depth of one or two feet, and the float ore obtained. We found float ore of a lower grade over the ridge, northward. No lode or deposit has yet been found. There are several benches dug in the hill, and a shaft 40 feet deep, but after 20 feet no ore was obtained in the shaft. A tunnel is being run, but no ore is found in the face as yet.

The surface of the limestone, for a depth of a foot or more, contains hunches of quartz and quartzite which are rich. But the find can only be taken as an indication. Some of the richest silver ore we have seen came from here. One lump found on the surface contained 300 pounds, others of one-half or less. Some 10,000 or 12,000 has thus been obtained.

There is a contest in regard to the title, both locations being on the same ground, and when we visited it we found it in the hands of armed men.

The Country is Stakad

For miles. From Lake valley on the south (which is the south end of the Black range), to Perche on the north, a distance of 25 miles in an air line, the country is claimed, and by whom? Echo answers, whom? To those who contemplate coming, we say: Capital is what is wanted, not only to develop the claims, but to find out who owns the unnumbered claims. Lahorers and mechanics are abundant. The country is young, only lately having been wrested from the Apache, who may at any time swoop down on the inhabitants. We think, from an extensive acqnaintance with New Mexico, that the Black range is the best mining section, and the recent finds are marvelous, indicating this as the coming country. Wood is abundant, with some good timber, but water is no go. The Perche river is only one in name. At Kingston there is not more than four or five inches in the stream, but it can be obtained by sinking. Winds, like those of Nevada, sweep over the country at stated times, one of which we experienced, which, in an instant, wrecked the canvas house in which we were sleeping, injuring us so as to lay us up for a week.

Recent Contributions to the California State Mining Bureau.

Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANKS, State Mineralogist.]

Successful Patant Solicitors.

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their agency from week to week and year to year.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter*.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

GRAFTING-WAX.—Thomas McLoughlin, Judsonville, Contra Costa county, Cal. No. 266,858. Dated Oct. 31, 1882. This composition or this grafting-wax consists of certain peculiar ingredients, combined in the specified proportions. In using this wax it is applied while in liquid state, by means of a brush, to the graft. When cool it becomes hardened upon the graft. In grafting the scion is tied to its place on the stock by means of a cloth bandage, and the wax used is put over and around the bandage. There are two main requirements in the use and formation of all grafting wax. First, it must, when applied to the cut, completely exclude the air; second, it must be weather-proof to resist the action of the sun and rain. There is a composition in general use for this purpose in which the ingredients are beeswax, resin and tallow, combined in various proportions. This composition serves the purpose very well; but it has been found by experience that by adding black pitch, honey and pine-pitch to these ingredients, all in certain proportions, a better wax is obtained, more economical because of the increase in bulk caused by cheap materials, and more efficient because of greater durability. The black pitch is the ordinary pitch of commerce, and its presence adds to the bulk, makes the composition stiffer when cooled, and renders it more durable and better adapted to withstand the elements. The honey makes it more homogeneous, and the pine-pitch, which should be gathered fresh from the trees, adds its turpentine to render it more capable of being molded or pressed around the graft. The composition may be preserved indefinitely, and when about to be used has but to be melted again. When around the graft and hardened by cooling, it makes an air-tight covering and will not soften in the heat of the sun, nor be beaten off or dissolved by the rain. It is clean to handle, is not sticky, and may be packed in cans or boxes to advantage. Compositions of similar character have been made before, but this of Mr. McLoughlin is a peculiar one.

HAME-CLIP.—Charles M. Derrick, Howland Flat, Sierra Co., Cal. No. 266,678. Dated Oct. 31, 1882. This invention relates to an improved hame-clip for harness, and more particularly to a novel means for vertically adjusting and securing the tug thereon. The invention consists in a vertical pintle held between supports from the hame, and in two hooks sliding on said pintle, the ends of which are adapted to engage in a series of holes in the hame when the pintle is in place. Between the hooks the tug is held upon the pintle. The object of this invention is to provide an improved means for vertically adjusting the tug for high or low draft.

Our Agents.

Persone interasted in incorporations will do well to racommend the publication of the official notices of their companies in this papar, as tha chaapast appropriate medium for advartiaing.

Land Purchasers' Association.—Location of principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors or Trustees, held on the 3d day of October, 1882, an assessment of Four Dollars ($4.00) per share (being a part of the 44th installment on the subscription to the stock) was levied upon the capital stock of this corporation, payable immediately to the Secretary at 318 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on MONDAY, the Thirteenth (13th) day of November, 1882, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on WEDNESDAY, the THIRTEENTH (13th) day of DECEMBER, 1882, to pay the delinquent assessments, together with the cost of advertising and expenses of sale.

C. S. WRIGHT, Sec'y.

OFFICE—318 Montgomery street, San Francisco, California.

N. B.—This assessment is to pay the taxes on the property of the Association for the current year.

DIVIDEND NOTICE.

OFFICE OF THE

Bulwer Consolidated Mining Company.

San Francisco, Oct. 25, 1882.

At a meeting of the Board of Directors of the above named company, held this day, Dividend No. 12, of ten cents (10c.) per share, was declared, payable on MONDAY, November 13, 1872. Transfer books closed on Thursday, November 2, 1882, at 3 o'clock P. M. This dividend is payable at the Farmers' Loan and Trust Company in New York on all stock issued there, and at the office in this city on all stock issued here.

WM. WILLIS, Secretary.

Office—Room 29, Nevada Block, 309 Montgomery Street, San Francisco, Cal

WATER JACKET SMELTING FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN SIXTY of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to examine mines and to superintend construction and running of furnaces. Estimates given upon application.

Send for circular.

"THE $1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

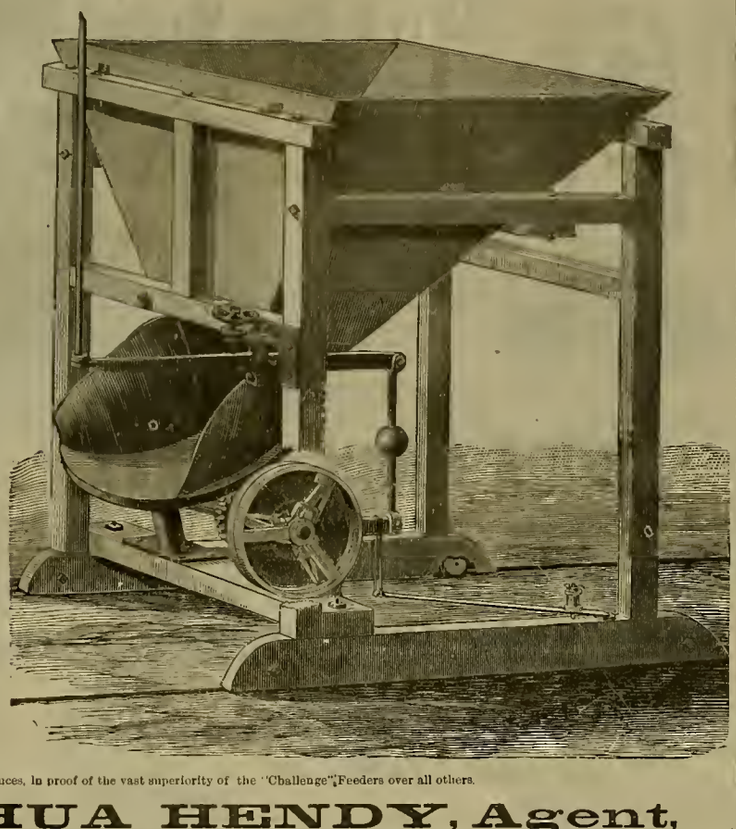
OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.



The Challenge Ore Feeders are now in Use in the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Uintah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

The "Harshaw" or "Heimoss" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King" Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sola" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

JOSHUA HENDY, Agent,

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are Infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞ The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

THE CONSUMERS' COMPANY.

VULCAN B B,

The Best Low Grade Explosive in the market. Superior to Black or Judson Powder

VULCAN NOS. 1, 2 AND 3,

The best Nitro-Glycerine Powders manufactured. Having secured large lots of the best imported Glycerine at low prices, we are prepared to offer the mining public the very strongest, most uniform and best Nitro-Glycerine Powder at the very Lowest Rates.

SPECIAL INDUCEMENTS IN PRICES.

Vulcan B B Powder (in Kegs or Cases) is Unequaled

For Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

The Central and Southern Pacific Railroads Use Vulcan Powder and no Other.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequaled by any other published embracing the subjects treated. Post-paid, $7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. A valuable and carefully written work. Postpaid, $3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by Dewey & Co., S. F.

PHILLIP'S EXPLORERS' AND ASSAYERS' COMPANION (Third Edition). Price of Vol. 1, post-paid, $6. Sold by Dewey & Co., S. F.

COPP'S AMERICAN MINING CODE, to replace Copp's Handbook of Mining Laws, now out of print. United States, State and Territorial Mining Laws and Land Office Regulations; Digest of Land Office and Court Decisions; List of Patents Issued and Dr. Raymond's Glossary with Form for Mechanics' Liens, Location Notices, etc. Price, postpaid, in paper, 50 cts. Sold by Dewey & Co., S. F.

THE EXPLORERS' MINERS' AND METALLURGISTS' COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 Pages and 83 Engravings. Price, bound in cloth, $10.50. Sold by Dewey & Co., S. F.

CHURCH'S "COMSTOCK, LODE, ITS FORMATION AND HISTORY."—Illustrated with diagrams and colored charts showing sections, ore bodies, etc. Post-paid, $7.50. Sold by Dewey & Co., S. F.

U. S. MINING LAWS AND COAL LAND LAWS.—Containing instructions and blank forms. Postpaid, 50 cents. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

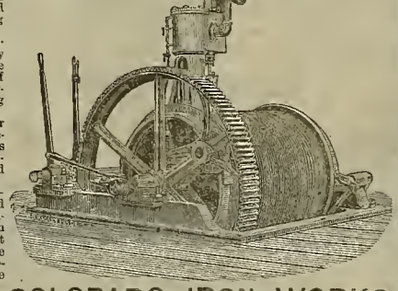
MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupellation Furnaces, Market Kettles, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.



COLORADO IRON WORKS,

P. O. Box, 1921, - - - - Denver, Colorado.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequaled strength, toughness and durability.

An invaluable substitute for forgings or cast-iron requiring three-fold strength.

Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.

15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.

CRANK SHAFTS, SHOES, DIES and GEARING specialties.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIOH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

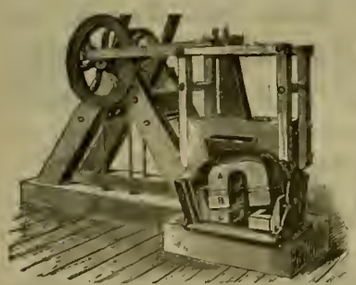
Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

MILL AND MINING MACHINERY.



Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by

F. A. HUNTINGTON, 220 Fremont St., S. F., Cal. | FRASER & CHALMERS, 145 Fulton St., Chicago, Ill.

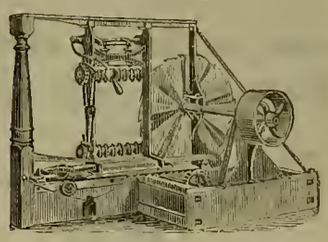
PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in very short time. One machine will concentrate the tailings from a five-stamp battery.

☞ Send for Circulars. ☜



SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

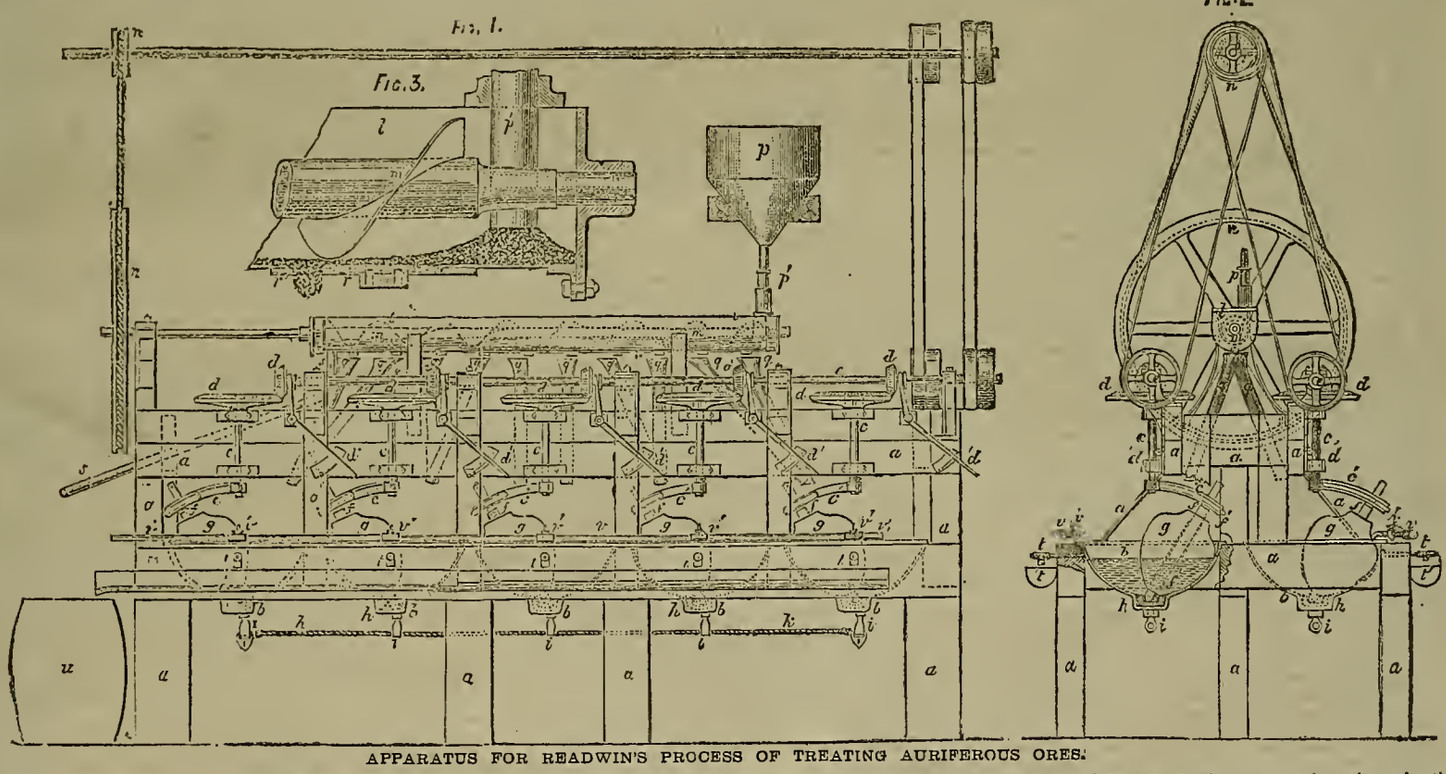
New Treatment of Auriferous Ores.

In this country the extraction of gold from its ores has only ranked as a commercial industry a little over a quarter of a century, yet the progress made, both in the extraction of the precious metal and in the mining of the ore, has been so rapid that, judging from external appearances, one would be disposed to class it among the businesses carried on from time immemorial. The treatment of gold ores as long carried on in the old colonial dependencies of Spain, in South America, was so unquestionably slow as to bear no comparison with the processes which have since become common on the Pacific Slope, and it may be safely said that many million tons of auriferous material which has been made to yield now plays a prominent part in obtaining other previously rare metals, was looked at with amazement if a lump the size of a walnut was exhibited, and the production of aluminium and magnesium on the commercial scale was still more recent.

The occurrence of salts of gold in nature has been confidentially declared by the few for a longer period than aluminium and magnesium have been in the market, and perhaps the best demonstration of the opinion being justified is the fact that mineral ascertained to contain little, if any, free gold extractable by any previously known process has in the hands of Mr. T. A. Readwin been made to yield up the precious metals in quantities which leave a handsome profit upon the treatment. This being so, it really matters little what may be the scientific views entertained upon the subject; if ore previously unworkable be made to yield a good return upon the money expended in mining and treating it, capitalists will be quite contented to leave scientists to think what they please. Already Mr. Readwin has confirmed the excellent results he has been obtaining at Glasdir by treating any auriferous ore sent to him for testing, so that there is now general confidence that reliance may be placed upon his process. In connection with the process, Mr. Readwin has just patented the machinery of which the above is an illustration, and in the final specification just lodged it is explained that the invention has reference to that kind of machine used for grinding ore and amalgamating gold or silver with mercury, wherein by an arm carried round by a vertical spindle suitably driven a pestle is caused to rotate about its own axis, and to roll obliquely on the inner surface of a circular pan, whose half vertical section is of a form resembling that (as seen in corresponding section) of the rounded surface of the pestle.

In machines of this kind, as heretofore usually constructed, considerable wear takes place in the bearings of the vertical spindle (to which neither oil nor grease can safely be applied); also in the pestle axis, also in the mercury cup at the bottom of the pan; moreover, considerable loss of time arises, owing to the irregularity due to hand feeding, and there is no efficient provision against unauthorized withdrawal of the contents of the pan. Now, according to this invention to obviate or mitigate these defects, the bearings of the vertical spindle are formed of hard wood or asbestos, and water is used as a lubricant. The pestle axis (heretofore usually made in one piece with or cast in the pestle body) is made of hardened steel or phosphor bronze, and removable from the pestle body, and is fixed therein in such a manner that it can be shifted lengthwise or renewed at pleasure. The pan is recessed at the bottom, and a square tapered hardened steel or phosphor bronze cup is placed in the recess to receive the lower end of the pestle axis, which works therein. A long trough is provided to supply the entire set of pans; in this trough a screw is caused to revolve, so as to gradually propel any material placed in it from one end of the trough towards the other. For each pan there is an aperture, through which, as the material travels along the trough, some of it falls and is conducted to the pans, the quantity supplied to the pans being regulated by suitable means. According to one arrangement for this purpose, each of the apertures in the trough is provided with a chamber of specific gravity, having inlet and outlet doors or valves, which are opened and shut at regular intervals, by screws or gearing, operated by the driving shaft placed over the machines.

Another arrangement to produce the same effect consists of (for each pan) a boss on the screw shaft carrying a cup or cups which shall dip into the material, and discharge the required quantity into a shoot in a specified time (the apertures in the bottom of the trough being in this case dispensed with). According to the arrangement which he considers most advantageous he forms outlets at the bottom of the trough with adjustable shutters which may be regulated so as to allow the required quantity of ore to pass through in a given time. The bottom of each pan is provided with an eyed tap screw, a wire or bar (which may be composed of wires stranded together) is put through the eye of each tap screw in a series, and is secured by means of a lock and key. In the diagram Fig 1 is a side elevation of a grinding and amalgamating machine, embodying his invention and comprising a set of 10 amalgamating pans fitted with gyrating pestles. Fig. 2 is an end elevation, partly in section of the right-hand or driving end of the machine. Fig. 3 is an enlarged sectional elevation of a portion of the feeding trough; *a* is the framing of the machine which supports the pans, *b*, of which 10 are here shown by way of example, and as being a convenient number, but more or less may obviously be employed; *c* are vertical shafts driven by gearing, *d*, from the driving shaft, *e*, the gearing, *d*, being disconnected when required by shifting the pinion out of gear along the shaft, *e*, by means of the levers, *d'*. These shafts, *c*, carry each a hooked arm, *c'*, in which freely rests the axis or spindle, *f*, of the pestle, *g*, so as to carry the pestle round, at the same



APPARATUS FOR READWIN'S PROCESS OF TREATING AURIFEROUS ORES.

profits in the Western States would have been condemned as worthless or intractable in Brazil or other countries of South America.

Of course we have by no means reached perfection yet, though each step on the road is watched carefully by gold miners. The following, therefore, from the London *Mining Journal*, will be read with interest: Thirty years ago the treatment of gold associated with sulphides was declared to be incapable of yielding profits, whilst at the present time that very class of ore now yields most of the wealth of the gold districts, so the now disputed occurrence of salts of gold in nature may be verified in such a manner as to prove immensely profitable to those earliest in the field of investigation on the commercial scale. It will readily be acknowledged upon glancing at a list of the now recognized metals, sodium, aluminium, magnesium, being worthy of mention as being familiar to all, that many of them were either absolutely unknown at the beginning of the century, or so extremely rare that only a few of the most celebrated chemists had ever had the satisfaction of seeing them, yet at the present time they are of considerable industrial importance. Even 30 years ago sodium, which

(CONTINUED ON PAGE 332.)

Breathing in Bad Air Underground.

An Apparatus for Miners' Use.

At the North Staffordshire Institute of Mining Engineers recently, a paper was read by the President on appliances of mining, in which full reference wae made to an apparatus for entering mines where there were foul gases. It may be recollecoted that upon the Comstock not long since thsre was great need for an apparatus of this kind, and that by means of one extemporized appliance great good was done. Miners will read with interest a description of the apparatus in use in England. The apparatus of Messrs. Fleuss & Duff enables them to go into mines provided with their own oxygen.

The Royal Commission investigated the appliance and refer to it in their preliminary report. Twelve months ago the apparatus had not been practically tssted in minss. It had been tried nnder water in various ways, and had performed good service at the Severn Railway Tunnel, where it enahled the workmen to go a quarter of a mile under the eetuary in a heading full of water, and close an iron door, which was necsssary to be done before the water could be pumped out. Within the past year the apparatus and lamp have been severely, practically tested in noxions gases in mines upon two occasions. About March last, at the Netherseale Colliery, in South Derhyshire (in the Ashby-de-la-Zouch coalfisld), Mr. Robert Howe, the manager, was enabled to penetrate for some distance from the pit bottom in an atmoephere of noxious gases, reeulting from a serious underground fire, and wit'out taking fresh air forward. But the most impoitant test of the apparatus was after the Seaham explosion, which enabled the viewers to make eome important explorations. I sought for and obtained some details as to the work done by the apparatus and lamp. I then communicated with the inventors and asked if they would favor us with their presence to-day, and you will he glad to see they are here. As I have before said, a year ago this was practically an untried invention for mining purposes, and the inventors were most anxious for it to be tested. I think it is eo interesting a subject that, with your permission, I will read a report furnished hy Mr. Corbett, chief mining agent to the Marquis of Londonderry, upon the application of this apparstus. Mr. Corbett saye:

"I was indnced to give a trial to Fleuss' patent breathing apparatus, and Foster & Fleuss' patent lamps, when opening out the Maudlin eeam at the Seaham Colliery. The circumstances, briefly stated, were, in consequence of an explosion, a large fire exieted in some temporary underground etahles; through this the eeam of coal caught fire. Brick etoppinge were inserted in the commnnications with that eeam and the air was totally excluded. After thue being hermetically sealed for eight monthe one stopping was broached and tbe workinge were found full of fire-damp. From thie broacbed etopping we had to brattice the way down to the eeat of fire, and it wae in this work we made uee of the patent breathing apparatus and lamp. Our men were enahled, by using the patent breathing apparatue and lamp, to penetrate the workinge, which were filled with gae, to a considerahle distance—in one inetance upwards of 300 yarde in advance of the bratticed air, and were able to report ae to etate of roof, road, etc. In putting up the brattice the lamp wae of the utmoet use, ae it could he used with perfect eafety in gae eo diluted with air that it wae of a most dangerous natnre and would fire in the common eafety lamp. We were frequently enahled to continue the work when we ehould not have been able to do so had we ueed the ordinary safety lamp. I conceider both patente to be of the greateet value and service in casee like the one above referred to, and have pleaeure in teetifying to their practical ueefulneee and safety." That ie a most important and gratifying result. At the riek of wearying you I shall be tempted to read a report by Mr. Sept. H. Hedley, which goee more at length into the matter.

What I have read relatee to Seaham, and what I am about te read is a description of the use of the apparatue at the eame place. Mr. Hedley eaye: "June 10, 1881. This being the firet trial of the apparatus, I only had it on for about 15 minutes, 10 minutee of which I spent in a room filled with ordinary coal gas and five minutee in a hoiler ehed filled with smoke from the boiler flues, and I found no difficulty in managing the apparatus June 11, 1881: I had the apparatus on about 35 minntes in an atmoephere of enlphur fumee, produced by putting rock eulphur on red-hot iron. The room was so hot that the skin of the face in unprotected parte peeled off. During the experiment I found no difficulty in breathing. June 13, 1881, I had the apparatue on for ahont 20 minutee in a room filled with ordinary coal gas, and again experienced no difficulty in breathing, and found myself getting ueed to the working of the apparatns. June 24, 1881: This experiment wae made for the purpoee of ascertaining how long it would be poeeible to live with the apparatus on. The chamber wae filled with ordinary coal gas to euch an extent that it was impossible for any one to remain in it without the apparatus on for two minntee without feeling eick and giddy. After being in the room an hour and a half I had to come out, owing to the bande around my head (which are necessary for making the maek airtight) causing me pain. Before returning I pnt on Danayrouzs's goggles and mouthpiece, and remained in the room one hour and 50 minutes more, thns proving that it was possible to live three honrs and two minutes with the apparatus on in an atmosphere in which it would he impossible otherwise to live. Thie experiment was made with only one charge of oxygen, and I have no doubt, with a little more practice, it would he possible to make the charge last four hours or more, as stated hy Mr. Fleuss. I felt no ill effect result from the long expsriment."

These experiments were made to test the use of the apparatus hefore going into the mine with it. They went into the mine on the 29th of June, and as to what took place Mr. Hedley writes: "This was the first time I used the apparatue in the mine, on which occasion I went with two othere into tbe workings for the purpose, if possihle, of reaching the seat of the fire. We penetrated the workings for a distance of 400 yards, from a point where there was no air. The hight of the passage for the first 100 yards was from 3 ft. 8 in. to 4 ft., and bsyond that distance about 6 ft. The road was fairly good, except where we had to pase over a few heavy falls of roof. The atmosphere of the mine was pure carbureted hydrogen gas, which would have extinguished an ordinary safety lamp. When I had traveled about 400 yarde one of the party felt his lege giving way, and, as it had been agreed before starting, that if anyone of us felt anything wrong we all had to return at once, we did so. On getting into the fresh air I felt a little excited, but it soon passed away. I went again into the mine with Mr. Fleuss and another. The falle having bsen ridded, and the gas cleared out to within 100 yards of the stahles (the seat of fire), beyond this point traveling was difficult, owing to the passage being heavily fallen. The atmosphere was the same as on June 29th. When we got to the high end of the etahles it was closed, and the fire bad not reached that point, as the coal was not charred and the etone wae about its natural temperature. The breather, as an apparatus for use in impure atmospheres, ie, in my opinion, a very good and valuable invention, hut it would not be safe for any person to use it for the first time in dsngerous gases, as practice is nesessary to enable one to use it with confidence. I found the mask, as previously stated, painful after using a ehort time, owing to the pressure of the bands on the head. I found the goggles and mouthpiece more convenient, also, I think, more economical, as with care, there can he no leakage of oxygen. This, however, is merely my opinion; others may prefer the mask. I found hy my experience when wearing the breather that it was important to take time, and not hurry or get flnried or out of breath and not to breathe deeply, and to avoid taking ehort breathe. And I feel confident if we had not hurried as we did the firet time we used it in the mine we wonld have been able to penetrate a greater distance into the workinge. I attrihnte the giving way of the legs experienced hy one of the party entirely to the epeed we traveled. It must he horne in mind that we were exploring in a part of the mine where there wae no ventilation and the natural temperature etande at 78 degrees. The lamp acted perfectly in the most dangeroue mixturee of gas and air. The drawhacke to it are ite eize and weight, and the liahility of the line to hreakages, if in traveling it receivee a blow hy etriking the eidee or the bottom of the paeeagee of the mine. I would euggeet to explorere using the apparatue and lamp that it ie desirable, where practicable, to have a connection with the persone remaining behind either hy a rope or otherwiee, so that in case of accident it could he nsed and othere could go to the aseietance of the explorere. Theee notee are written for the purpose of giving the experience gained in the use of the apparatus and lamp.

Boys' and Girls' Aid Society.

Thie association ie one which deserves aid and encouragement on account of ite practical reeults. Since May 1et, a period of only 24 weeke, it hae given 1800 lodgings snd 4411 meale to friendless children. It hae also distrihuted among these homeless onee 906 articles of clothing. If has found employment for 98 boys and girle in this city, and has found homee for 132 othere; 70 of the latter were taken directly from the courts or prieons.

Ite objecte are worthy, and it eavee many children who otherwise would eoon have been numbered among our criminale. Until euitable homee can be found for theee neglected children, it providee quarters with which are connected reading-roome, bathe, a gymnasium, eavinge banke, a echool of cookery, a sewing echool, a clase in music and classes for instruction in other branches. Lectures and entertainments are given for the instruction and amusement of the children, and a temperance organization ie connected with the eociety.

At preeent the eociety is greatly in need of money for the proeecution of the work; aleo, homee and employment for children. Clothing for both eexes, and all ages, ie earnestly requested. Ladies and gentlemen in every town to whom the eociety can look for information in regard to applicants for children, and through whom children placed in their vicinity may communicate with the eociety are greatly needed. The society ie eituated in the midet of our city and should receive the attention of the creditably diepoeed. Communications or parcele should be addreesed to 68 Clementina etreet, S. F.

A Rich Montana Mine.

The editor of the Helena *Independent* bas recently visited the Boston and Montana company's Gloster mine. Ahout 200 men are directly or indirectly connected with the operatione of the company. Nsarly 150 are in the mine, the two etamp mills, and the saw-mill, besides the wood choppere snd others remotely connected with the plant. One of the first thinge that impresses one on arriving at the large mill ie its solidity. It is an imposing etructure and is planted on the solid rock. An excavation 115 feet long and 35 feet deep was made along th margin of the rocky bluff near the junction of e small gulch with the main one, in which hoth mills stand, and on this stone foundation the largeet battery tinhere ontainahle—and there are no larger ones in the Territory—were placed. The good effect of this solidity is apparent not only in the movement of the ponderous machinery, whichie as free from jar and irregularity as the mountain itself, hut the very noise of the stamps is suhdued on that account, and one is fairly surprised to find that 60 stamps in action should make so little racket. At the main shaft of the mine is the new ehaft house, 100x32 feet, and the carpenter-ehop, 100x20, hesides the boiler house, 36x40, all under one cover; and hy tho 25th of thie month the new hoist will be ready for use. Adjacent to it a hin is being constructed which will hold a thousand tons of ore, and with the bin the tramway will he connected The present output of tbe mine is ahout 90 tons of ore from the shaft and 25 tons from the upper works of the mine through tbetunnel. As soon as the cages hegin to run, the ore will be left in the upper works and that taken which is in the deeper parts of the mine, where the grade is better, and the results of the runs will doubtless be greatly enhanced in value. In one of the stopss visited the vein was nearly 20 feet wide, and Alex. Swan, the gentlemanly superintendent of the mine, says that he could keep the mills steadily at work on ore now in sight in tbe mine for two years, if no more ground should he opened. It is evident, however, that a long life is hefore the enterprise, for as progress is made into the new ground easterly or into the hill, tbe vein improves, and there are yet 600 feet more ahead of the hreast of the east level. Now that the expense of construction is passed, the income of the mine will again he turned over to the stockholders, and on the 6th of nsxt month a dividend of five cente per share of the capital will e paid in New York and Boston. A surplus will he left, hut it is thought advisahle to let the overplne accumulate after each dividend until snch time as it is deemed advisable to declare extra dividende. On Friday last retort weighing 1,206 52 ouncee wae hrought in from thie mine, the value of which ie ahout $15,000.

Coal in Idaho.

A. L. Rinearson, of Boise, hrought to the *Times* office to-day a chunk of bituminoue coal taken from a claim which he owne near Horeeshoe Beud on Shaffer creek, about 20 milee north of Boise. The vein ie 40 inches wide, the formation is pronounced similar to that near Danville, Ill., and the coal is pronounced of excellent quality hy all who have eeen it. Several teete have been made of it in Boiee, and theee were eo eatisfactory that the fire department of that city have agreed to uee it in their engine and etoves, for raising eteam and heating, to the excluelon of all other fuel. Surveyor General Chandler, who has had 25 years' expereience in coal minee, pronounces it a good bituminone coal.

Mr. Rinearson hae five men at work on the claim, driving an entry on the vein. Several tone are already extracted and will eoon be hauled to Boise, where they will be distributed among the families, blacksmithshops, etc., and a thorough test of it thus made.

Mr. Rinearson's claim wae discovered by the outcrop, which ie remarkably hold and massive, but the vein does not crop out for any great length. Five milee from hie claim, on a line drawn at right anglee with the etratification, a five foot vein of lignite was discovered and located, last fall, by Mr. Krebs, the Receiver of the Boiee Land Office, and a sample lot wae sent East for testing and analyzing. The reports received were to the effect that the lignite was an excellent fuel, that it was euperior to charcoal for smelting and other furnaces, and that in depth it might even prove more desirable for that purpose than coke.

Mr. Rinearson ie of the opinion that ae eoon ae the Oregon Short Line road ie completed to Boiee, the people of Wood River will go to that place for much of their fuel for all purpoeee.—*Wood River Times.*

Shoes Without Leather.—Anna Kingeford, M. D., the learned authoress and lecturer on vegetarianism, in her efforts to live without consuming any animal product requiring the sacriiice of life, has at last found a shoemaker who has made for her a perfectly satisfactory pair of shoes. The uppers are made of *panus carium*, and the soles of some other vegetable composition. She writes: "I have worn them with perfect comfort, and the cloeest obeerver would not know them from ordinary shoes." It will be remembered that Dr. Kingsford contributed an able paper to the *The Herald of Health* recently on "Food and Education."

Treating Metals and Alloys.

An improved method of treating all kinds of metals and metallic compounds, which consists in subjecting them when raised to a temperature sufficiently high to ensure the necessary ductility to powerful compression, and then allowing it to become completely cool while still under pressure, has been patented hy Mr. Louis Clemandot, of Paris. The nature of the metals after undergoing the three phasee of heating, compression, and cooling under pressure is considerably modified, the grain is rendered much finer, and the density of the metal considerably increased. Metals thus treated undergo a kind of mechanical hardening, and acquire a degree of hardness and density hitherto unattainahle. Steel in particnlar may be said to receive a peculiar temper by compression, by which it acquires coercive propertiee and hecomes permanently magnetic. With regard to the phenomena due to the application of this method of treatment, it would appear that the compression and cooling of the metal under pressure present the molecular stateof the metal in a peculiarly favorable condition for homogeneousness; the solidified metal may be said to he amorphous, whereas the contrary is the case in the ordinary cooling of a metal in which crystallization or a tendency to crystallization may occur.

It has been stated that tbe metal is, before compression, heated to a sufficient degree to render it ductile enough for the purpose, and this may be done either hy reheating the metal or by taking it at any suitahle stage of its manufacture. For very soft metals, such as certain kinds of alloy, the employment of heat is not essential, and the process of compression may, therefore, he applied to metals or alloye in a cold etate, according to the results it is desired to obtain. It is claimed that by this method of treating metals and metallic compounds their quality is much improved; for example, steel, heretofore unsuitable for tool making, will, after being treated according to this process, be rendered of very good quality for the purpose. Moreover, this treatment when applied to metals in course of manufacture, will permit of the association therewith of still larger proportions of substances employed to modify their properties, according to the purpose for which they are to be employed. This improved method of treatment is applicable to all the metals, including wrought, cast, or malleable cast iron, steel, copper, zinc, gun-metal, bronze, brass and nickel, and is, therefore, eusceptible of a great number of application, but is more especially applicable for producing excellent qualities of steel for magnets, rails, tools, files, gravers' cutlery, coiners' dies, coins, machine hearings, etc. The mechanical means employed for the compression of the metal may he any suitahle kind, but it ie preferable to nee hydraulic power when available as being more powerful, easily regulated, and, at the same time, more readily applied in the different caeee enumerated.

Mining Near Calistoga.—People who believe that the mining business in tbie locality is eo dead that it will never he reeurrected, are greatly mistaken. The fine prospect in King Canyon, over which there wae so much trouble, still remains there, and though work ie not now heing done, it is by no meane the intention to let mattere drift indefinitely. There will yet he a good mine in King Canyon, and there will aleo he a good mill in th at vicinity to work the ore. R. F. Grigsby, whose name in connection with the business of mining is familiar with mine-owners and capitaliete, ie eecuring controlling interest in diff rent claims. He ie a capital miner, well understanding every thing pertaining thereto. He will yet snperintend and control minee of importance in this vicinity. There ie plenty of good milling ore here, and he ie the right kind of man to take it out. Work on the Good-enongh claim wae euspended several daye ago, after there having been a shaft sunk to the depth of fifty feet—a very large flow of water interfering, thus necessitating the erection of a large pump or the sinking of another prospect ehaft elsewhere on the claim. Work ie being done in the ehaft on the Consolidated Ohio claim with the intention of sinking it to a depth of at least fifty feet, and further if there are changee of importance. The vein improves ae a greater depth is attained, and the owners entertain strong hopee that the improvement will be very marked at the depth mentioned. The tnnnel of the Mountain View is now in a distance of 113 ft. Work on this claim has been resnmed thie week. —*Calistogian.*

Petroleum in Russian Locomotives.—This ie the way petroleum ie burned in the firebox of a Ruesian locomotive: "The refuse is laid on the highest step at hoth ende of the firebox, and drops from one etep to the other, cascade faehion. No steam is introdnced into the firebox, ae the refuse petroleum simply rune through the pipes by gravitation, the tank carrying the petroleum being placed not on the floor of the tender, hnt above the water tank, and ehonld the petroleum be too thick, it ie arranged that steam can be introduced through a warm pipe in this tank, the eteam ultimately exhaueting into the tender."

Practical Effect of Cold on Iron.—Careful observatione on Rueeian railways have reeulted in ehowing that for a period of six monthe 77 per cent. of the fractnres of tires occurred when the temperature wae below zero, and only 19 per cent. at higher temperatnree.

MECHANICAL PROGRESS.

Zinc in Boilers.

Since 1875 experiments have been carried on in the French marine, particularly with boilers having surface condensers, to test the efficacy of zinc leaves in neutralizing the effect of fatty acids in the boiler and giving rise to inoffensive products. Commandant Frene has recently given an account of the results obtained on board the *Desaix* to the French Academy of Sciences, of which *Engineering* gives the following summary:

The zinc inside and the iron of the boiler constitute a voltaic element which decomposes the water and liberates oxygen and hydrogen. The oxygen forms oxide of zinc, which combines with the fatty acids mingled with the feed water, thus forming "soaps" of zinc, which, coating the tubes of the boilers, prevent the adhesion of the salts left by evaporation. It is easy then to brush away the fixed matter on the tubes, which is in a mealy state. As to the hydrogen, it behaves as MM. Garnez and Donny have described in the *Annales de Chimie et de Physique* for 1875. Ebullition takes place by evaporation at the surface of a gas, whether dissolved in the liquid or clinging to the solid envelope of the containing vessel. If the gas is expelled from boiling water, the latter can be superheated to 30° or 40° Cent. above the normal boiling point, and in such a case evaporation only takes place at the surface. When the temperature of the vapor emitted corresponds to the tension which equilibrates the pressure exercised at the surface of the liquid, the ebullition can be started at will by introducing a gas bubble into the liquid. Solid bodies operate in the same way by reason of the film of gas adhering to them. When by long boiling all the gas is expelled, the water becomes superheated, and thus an element of danger is introduced. But by the employment of zinc in the boiler a constant supply of gas is maintained, and all danger of superheating is avoided. The hydrogen not only starts the boiling, but keeps it up. It is, however, necessary from time to time to take out the zinc plates from the boiler and clean from them the salts adhering to them, else the galvanic action will dwindle and perhaps stop altogether. M. Frene is of opinion that the action of the zinc is, however, not so regular as theory might expect, and advocates the substitution of a sure and constant mechanical action under the form of a moderate but continuous injection of warm air by the lower part of the boiler, or, better still, a non-oxidizing gas, such as carbonic acid. This plan, he thinks, would produce a perfectly regular ebullition, a rapid evaporation, a saving of fuel, and freedom from risk. Superheating, which he figuratively calls a sleep of the liquid, would be no longer possible. The carbonic acid could be developed by the combination of carbonate of lime and hydrochloric acid.

American Inventions in the English Army.

The English army was largely indebted to American inventors for the accomplishment of their recent triumph in Egypt.

The most effective work was done by their turreted vessels—an American invention. All their war ships were supplied with the Brush electric lights, invented in Cleveland, Ohio. These lights were of very great utility. They not only indicated the points of attack by night, but also directed the movements of the ships, and were of special advantage in watching for and guarding against night surprises both upon ocean and land.

The American machine guns proved a most efficient arm for the invading forces. One vessel fired 6,000 pounds of shot from Gatling guns the first day of the bombardment. A handful of marines, with guns of this type, were able to disperse the Alexandria "looters," and restore order in the afflicted city, where many times their number would have failed without such aid.

In the subsequent skirmishing with Arabi's troops about Alexandria, and later in the capture of Shalnf and other fortified places along the Suez canal, the same gunboats and on shore have been in constant use.

Many of the small arms of the English soldiers are but slightly modified American guns, made with machinery patented after that developed in the shops of Springfield, Mass. The system of fixed ammunition for small arms also, and the machine by which such cartridges are made, are all of American origin.

Even all this does not exhaust the indebtedness of the British army to American inventors. Among the great quantity of supplies for the British army in Egypt mention is made of driving apparatus, tubing and pumps for 200 "Abyssinian wells," by which name American drive wells are known in England, from the circumstance that they were first used by the British army in the Abyssinian war. It is estimated that 200 wells of the capacity ordered will furnish from 2,000,000 to 3,000,000 gallons of water a day, and make the army independent of the surface water sources of the country. Seeing that the fresh water canals are largely in the control of Arabi, the success of the invasion may be largely contingent upon the ability which drive wells give of obtaining water anywhere in the desert.

Adhesive Power of Nails and Screws.

The extensive use to which nails and screws are put in construction lends considerable interest to any records of experience tending to discover their holding power. Haupt, in his "Military Bridges," gives a table of the holding power of wrought-iron rod nails, 77 to the pound, and about three inches long. The nails were driven through a one-inch board into a block and the board was then dragged in a direction prependicular to the length of the nails. Taking a pine plank nailed to a pine block with eight nails to the square foot, the average breaking weight per nail was found to be 380 lbs. Similar experiments with oak showed the breaking weight to be 415 lbs. With 12 nails to the foot square the holding power was 542½ pounds, and with six nails in pine 463½ pounds. The highest result obtained was for 12 nails to the square foot in pine, the breaking weight being in this case 612 pounds per nail. The average strength decreases with the increase of surface. Tredgold gives the force in pounds required to extract 3d. brads from dry Christiana deal at right angles to the grain of the wood as 58 pounds. The force required to draw a wrought-iron 6d. nail was 187 pounds, the length forced into the wood being one inch. The relative adhesion when driven transversely and longitudinally is, in deal, about two to one. To extract a common 6d. nail from a depth of one inch in dry beech, across grain, required 167 pounds, in dry Christiana deal, across grain, 187 pounds, and with grain 87 pounds. In elm the force required was 327 pounds across grain, and 257 with grain. In oak the figure given was 507 pounds across grain. From further experiments it would appear that the holding power of spike-nails in fir is from 460 to 730 pounds per inch in length, while the adhesive power of screws two inches long, .22 inch in diameter at the exterior of the threads, 12 to the inch, driven into ½ inch board, was 790 pounds in hard wood and about one-half of that amount in soft wood.

Transmission of Power by Wire Ropes

According to a recent treatise on the transmission of power by wire ropes, issued by the William Orton Manufacturing Company, of Sterling, Ills., the distance to which wire rope transmissions may be applied ranges from 50 or 60 feet up to several miles. As an example of long transmission, attention is directed to that of Schaffhausen, Switzerland, at the Falls of the Rhine. Here 800 horse-power is carried diagonally across the line, and extended for a distance of two miles, and there distributed among 50 different manufactories situated in every imaginable position, and embracing all the varied arrangements of changing directions. Wire rope transmission comes into use at the point where a belt or line of shafting becomes too long to be used profitably. In point of economy it is much cheaper than its equivalent, either in shafting or belting. This method has been extensively introduced in Europe, and with great success for several years past. It is now receiving a rapid development in this country. It has the advantage of transmitting power in any direction, up or down hill, across rivers, around buildings or obstructions of any kind, and thus make available many sources of power which are otherwise useless. The ropes hang free in air, and require no protection from the weather, except an occasional coat of warm coal tar, which may be applied to the rope by pouring from a can into the grooves of the wheel while running. Instead of coal tar, raw linseed oil may be swabbed on the rope to keep it from rusting, and thereby preserve it. The ropes run perfectly smooth and noiseless on vulcanized rubber filling, and are not affected in the least by wet or cold, snow or ice.

Care and Use of Belts.—In lacing a belt, always begin at the center, keep the ends exactly in line, and lace both sides with equal tightness. The lacing should never be crossed on the side of the belt that runs next the pulley. Use thin but strong laces. Belts should never be oiled except when they become hard and dry, and even then the oil should be used very sparingly. Oil not only rots the leather, by its own decomposition, but also causes the belt to stretch. In oiling or greasing a belt use only a pure thin oil. A thick, pasty oil is not good. Such oil will soon enter upon a process of decomposition and rot the belt.

Steam Road Carriages.—The principal cause of the lack of success in building a practical steam road carriage is the difficulty experienced in the efforts to so "hang" the engine and boiler that the carriage may run in any direction, or over ordinary obstacles, without seriously affecting the joint and machinery connections. So says an eminent mechanical writer. Even the English acknowledge this in their efforts to run steam road carriages over the exceptionally good roads of England.

Pneumatic Tube for Philadelphia.—The Post Office Department is considering the feasibility of putting in very large pneumatic tubes for the Philadelphia Post Office, connecting it with the mail depots in the city. The object is to avoid the slow transference of mails from trains by coaches to the central office. No steps as yet have been taken in regard to actually putting the plan in operation.

SCIENTIFIC PROGRESS.

Explosives from Tar, Pitch, Coal Dust, Etc.

New Researches.

Two years ago a process was patented in Berlin for making explosives from crude tar oils, by direct nitrations with strong acids, which mixtures, after being washed and dried, were oxygenated with chloride of potash and strong nitric acid. We give a brief digest of some further researches in this direction condensed from a German industrial paper—the *Zeitung*.

The success of the above process suggested the utilization of tar itself for explosives. Experiments soon proved that the treatment of tar with strong nitric acid was attended with much difficulty and danger. The subsequent use of an acid of 1.53 to 1.45 sp. gr. gave more satisfactory results.

The liquid tar is gradually stirred into the acid, the surface of which becomes covered with the tar, which on stirring settles slowly to the bottom. In about 10 minutes the mass at the bottom puffs up and gradually changes from a liquid to a pasty or solid state, until the acid has become saturated. The chemical changes do not produce any excessive heat, so that cooling is unnecessary.

The product is then thoroughly washed, and the purified product mixed with the oxygenating bodies above named. One part of the product by weight dissolves very slowly with the solution of but little heat, in three parts of nitric acid.

All the mixtures as proposed give new explosive compounds of different degrees of violence. Owing to the varying compositions of the tar, it is impossible to give the exact proportions in all cases in which the oxygenated substances should be added, but generally from two to five parts of chloride acid, or four to six parts of the salts were sufficient for one part of the nitro derivative.

The great advantages offered by this process are: Cheapness of the material to be acted upon; cheapness of the lighter acid used (a difference of 60%), and finally in the quiet and regular and safer manner in which the reactions take place, permitting the employment of more simple and less expensive apparatus, etc.

These successes led to further experiments upon the pitch, the paraffines, etc., as the mineral oils. The possibility of nitrating the latter seemed probable from their great similarity to the crude tar oils. Experiment, in fact, proved that they reacted exactly alike. But the strongest nitrating agents are required to act upon the purified mineral-oils used for illumination. A mixture of equal weights of the strongest nitric and sulphuric acids, or a mixture of an alkaline nitrate with sulphuric acid was employed.

On paraffines and similar products the weaker acids are as ineffective as on purified mineral oils. By the action of the nitrating agents mentioned upon purified mineral oils, nitro-compounds were precipitated of a light yellow or light brown color having the external appearance of rancid fat. These products are difficultly soluble even in the strongest nitric acid. Pitch treated with nitric acid of 1.45 to 1.52 specific gravity, gave a yellow-brown solution, and from this light yellow to brown scales separated on washing with water. The oil and pitch from wood tar were treated with the weaker acid (1.45), and those from brown coal and stone coal with stronger acid (1.52). The products thus obtained are easily soluble in strong nitric acid with slight evolution of heat. These nitro-compounds when mixed with oxygenated bodies also form powerful explosives, but the quantity of the latter used must be two to four times greater than that added to nitro-derivatives of tar.

All the special products of the distillation of coal having been found capable of being converted into explosives by nitration, it only remained to try an experiment on the original materials, coal and peat. Wood was excluded from the list for its conversion into an explosive (pyroxyleine) had already been accomplished by Trauzl. It was found that the direct conversion of coal into an explosive by extracting the nitro-products, would involve very expensive and tedious manipulations. The coal, in form of a fine dust, was first treated with weak nitric acid, specific gravity 1.40 to 1.48; the weight of acid required was ten times that of the coal used. When stone coal was introduced slowly into the acid the rise in temperature was inconsiderable, and some hypontric acid was formed. The action was much more violent in the case of brown coal, and least so with wood coal. After the operation with any coal, a large portion of the material to be nitrated remained apparently unaffected, and formed a thick sediment on the bottom of the vessel.

The results of experiments made on peat were considerably more encouraging, different kinds being tried. A firm, solid kind called "hog peat" was tried after a small test had shown that the reaction would not be too violent. It was first subjected to the action of equal parts by weight of the strongest nitric and sulphuric acids for several hours. The substance changed color from dark brown to dark red. Ignited in the air it burned with a lively flame and strong aromatic odor. When soaked in a solution of chlorate of potash and dried, it formed a powerful explosive. If the same peat was well pounded before the nitration, so that the humus substance was separated from vegetable fibers, and a larger surface was exposed to the powerful action of the acids, the earthy humus constituents were converted into a dark brown liquid, sticky nitro-body, have the external characters of that obtained by nitrating the heaviest tar oils. Its action, when mixed with oxygenated bodies is also just like the latter. The other nitro substance, formed from the finely divided fibers left in the dry distillation that attends the formation of peat, yields an explosive without any admixture of an oxygen-bearing salt. In the open air it burns very rapidly, leaving a slight carbonaceous residue. Peat containing animal admixtures acts just like this bog peat.

The manufacture of explosives from peat, owing to the cheapness of the material and its wide dissemination, as well as the simplicity of the process, is doubtless an important step in advance.

The chief characteristics of the newly prepared nitro substances are the following: The specific gravity of all is very nearly that of water. They all possess a powerful aromatic odor, resembling the fruit ethers, which is particularly noticeable on burning them. All solutions of these substances have a strong refractive power. The greater part of them are soluble in the strongest nitric acid as well as in alcohol. They are all insoluble in water. In the open air they all burn with a bright, but more or less smoky flame. Their molecules are so slightly united that they can be exploded alone or mixed with oxygenated substances by simple ignition.

Is Fingal's Cave the Work of Man?—At a recent meeting of the Geological section of the New York Academy of Sciences, Mr. F. C. Whitehouse exhibited, by means of the magic lantern, a large number of views of caves on the island of Staffa, the most interesting of which was a view of the famous Fingal's Cave. After fully describing their form, size, etc., Mr. W. surprised his audience by affirming his belief in the theory that they were not, as generally supposed, formed by natural causes, but that they are really artificial caves, made by the hand of man at some very early period. The speaker gave as a reason for his conclusion the shape of the roofs, which, in all known natural caves, are low and flatly arched; but here, in all cases, high, with Gothic arches like a Catholic church. Moreover, the rocks in which these caves are found do not crumble into irregular pieces, but keep their columnar form. If the caves had been excavated by action of the sea waves, their columnar remains would have been much more abundant as debris in the vicinity. They were probably taken out carefully and carried off, probably to Scotland, where many are found. The members were not generally prepared to accept the theory, but were very much interested in the discussion which was raised in regard to it. The subject affords abundant food for research and thought.

Artificial Silk.—E. Stutzer, of Berlin, has devised a method for producing goods with a beautiful silky lustre by mixing wool with vegetable fibers, such as flax, hemp, jute, etc. It is well known that in bleaching and dyeing in the ordinary way, vegetable fibers require an entirely different treatment from those of animal origin; but Stutzer has found that this unequal dyeing is due to the presence of a gummy substance in the cells of plant fibers, and he has devised a peculiar boiling process, with chemicals, which remove the gum and admits of uniform dyeing. It is also well known that when silk is to be mixed with vegetable fibers a similar difficulty is met with in dyeing the mixture; but Agache and Imbs, of France, overcame this difficulty by softening the vegetable fibers in an emulsion of animal oils with a solution of soda, and then piling them up in heaps until fermentation takes place. The plant fibers are moderated in this way, and then when mixed with waste silk can be spun like flax, wet or dry.

Magnetic Observations.—A series of magnetic observations, which are to extend over a space of 14 months, have recently been commenced at Goettingen, Germany. They will take place under the supervision of the professor of the University, on the 1st and 15th of every month at the same hours as those performed by the international expeditions sent out to the North and South Poles. Their principal object is to ascertain the magnetic condition of the earth. Experiments will also be made with respect to magnetic intensity in the garden of the observatory, in a pavilion built up of wood and brick only, iron being omitted on account of the disturbing influences which it would exert, rendering the observations practically valueless.

Crystallization of Silica from Fused Metals.—Dr. R. S. Marsden, on an examination of microscopic sections of some Berlin porcelain crucible which had been used in experiments with fused silver and amorphous carbon at a temperature considerably above the melting point of the former, found that, while the alumina part of the crucibles had undergone little change, the glaze had become a "mass of little crystals of a hexagonal form." Similar prisms were separated from the silver. The crystals quietly dissolved in hydrofluoric acid, while not acted on by nitric or hydrochloric acid. There were also leaf-like forms, apparently silica, which are not yet fully explained.

Mining Share Market.

There have hesn very slight changes in the prioes of mining stocks during the past week, as onr stock tahles show. The "visiting days" on the Comstock is a new feature. The principal object of appointing the visiting days was in order that persons interested in the mines might see for themselves the vast amount of work that has been done; also that they might see that it has all been done in the right direction at every point, and that all might see for themselves that the ground which is being explored is of such character as is likely to contain ore. On Monday last many persons visited the "north end mines," and were generally well pleased with the outlook. There was no great amount of ore to he seen, however.

The bottom of the joint Ophir and Mexican winze shows some quartz which yields low assays. The material ontside of the quartz presents a very favorable appearance. Operations at this point will he followed with great interest once the 3100 level bas been reached and drifting hegins, as the change of stratification promises other changes of importance.

The *Enterprise* says that in nearly all the drifts from the 2700 level down were seen promising seams and streaks of quartz which, from their carrying more or less metal, show the ground to he of a fertile character. It is the opinion of the experts that within six weeks or two months developments will he made which will result in very lively times in the north end stocks.

A Brazilian Mine and its Slaves.—A correspondent of the London *Mining Journal* contributes the following item: At length the final sentence has heen given in this celebrated case—judgment against the St. John del Rey Company on all points—and it is not only the culpability of having kept these blacks in slavery illegally for 20 years, hut the manner in which the case has been fought since 1877 to shield individnals from the consequences of their acts done under the name of the company. These blacks, now reduced from 385 to 155, are declared to have heen free nnder the clause to that effect in the contract dated June 27, 1845, and not by the letter of liherty presented, expressed to have emanated from the Brazilian (Catta Branca) Company 30 years after that company had heen officially declared to he extinct. A pamphlet has appeared respecting this precious document, and the proceedings of the St. John del Rey Company in their defense, and asking who manufactured this spurious letter of freedom. The hlacks are severally authorized to hring an action against the St. John del Rey Company for their wages from Jan. 1, 1860 to the time a Curador (Guardian) was appointed for them, June 22, 1877—*i.e.*, for 16 years, 5 months, and 22 days. This will carry interest and damages for keeping them in slavery till April, 1872, matriculating or registering them as slaves in that month, and from April till the end of the period; and from June 22, 1877, to Dec. 9, 1879, they are declared to he entitled to he paid their wages hy the St. John del Rey Company at once. This part of the judgment the St. John del Rey Company have heen endeavoring to compromise by offering the first-class hlacks the pitiful sum of about 10*l.* instead of the 90*l.* to 120*l.* to which some are entitled, so that the company are determined, if possible, to the last to get the better of these poor people. The Treasury has its claims allowed for the earnings of those who died in illegal captivity at Morro Velho.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Rich.—*Dispatch*, Nov. 11: Mr. James Morgen is having some of the rock taken from his mine in Murphy's Gulch crushed at the Moore mil, which is proving very rich in both sulphurets and free gold. The indications are that this mine will yet prove to he a good property.

Bunker Hill.—*Ledger*, Nov. 10: The Bunker Hill mine closed down last Monday, for an indefinite period. The mill is also idle, but the sulphurets works will run for a few days longer. The company are owing the employees considerable for wages. A proposition was made by the President to give the men a note payable in 90 days. A meeting of the miners was called to consider the offer. At first the men were inclined to accept it, if a mortgage on the property was given as security. At another meeting held last Thursday, however, there was some difficulty in the way, which determined the creditors to decline the proposition. A number of them came to Jackson this (Friday) morning, for the purpose of filing a mechenics' lien upon the property, which we presume will he done ere these lines reach our readers.

CALAVERAS.

West Point.—Cor. Calaveras *Chronicle*, Nov. 11: The benefits derived from early raine are beginning to be felt in this section. The quertz mills, that have been idle during the dry season for the lack of water, have now resumed crushing ore from several mines, giving a new impetue to the prosperity of this place. The mining boom of our district is beginning to make its advent here. Our much neglected mines will take a start which will rouse the envy of other less favored mining towns that have attempted to depreciate the mines here, consequently preventing capital from investing. The hoisting works on the Carlton mine are now completed. The shaft is 80 ft in depth, and sinking will be resumed this week and prosecuted until a depth of 200 ft is ettained. This will give 110 ft of etopes, and employment to about 40 men. The day is not far distant when the Carlton mine will yield handeome dividends. A sensation has been ceused in this place by the report that the Lone Star has been sold to an Eestern company for $25,000. The new owners will commence operatione on the mine in about three weeks. It is the intention of the company to erect a 20-stamp mill at the north end of the mine, on the left bank of the Mokelumne river. A large tunnel will then be run into the mountain and tap the ore bodies. Most of the work will be done by the aid of Burleigh drills. In the Star of the West sinking is being vigorously prosecuted. The ledge is large, with plenty or high-grade ore in sight. A 10-stamp mill will soon be erected near the mine. Rose & Jenkins have resumed operations on their mine. The Pacoe mine, owned by Henry Sterling, is still being worked. Water has been etruck in the main shaft, and a drain tunnel is being run. It is the intention to erect steam hoisting works on the mine.

EL DORADO.

Mill City.—*Mountain Democrat*: Mill City is situated on the north fork of the Cosumnes river, about two and a half or three miles from Grizzly Flat. It has recently taken its name from the number of mills lately built and now under course of conetruction there. There are at present four mills in working order, and soon another will be ready to etart up. These are as follows: The lower mill belongs to Mr. Lyons. Tbie has 10 stampe of 700 pounds each, the motive power being a Knight wheel, under pressure of about 65 ft. It is crushing at present about 22 tons in 24 hours. Next comes the Parlow or Flag Staff mill, about 50 ft above the Lyons, and on tbo same (north) side of the river. This is also a 10-stamp, of about 350 or 400 pounds each, now in operation, crushing about 10 or 12 tons in 24 hours, propelled by a Morey wheel with two etreame of water coming from the same ditch, with the same pressure as that of the Lyoos. On the opposite eide of the river, and about 300 yards above, stands the Melton, a 4-stamp mill. The mine was recently purchased by a New York company, and is superintended by H. H. McClellan, who is now constructing a new 10-stamp mill about 100 yards above the old 4-stamp mill. The stampe are 750 pounds each, high mortar, to be propelled by a 42-ft Knight wheel. The Bullard, standing between the four above mentioned and the new mills of the Meltou mine, is a heavy 8-stamp mill. Mr. Bullard has worked some of hie ore in this mill with satisfactory results. It is now idle while he is bringing in a new ditch. We nnderstand it is soon to start up again. In all there are five mills within a distance of a quarter of a mile, all built on the bank of the river, all using free water taken from the north fork of the Cosumnes, and all with good prospects. Where a few months ago nothing was to he heard but the rushing of tho water over the rocky bottom of the Cosumnes river, is now thickly studded with large new buildings, the noise of many stamps, hueytoams passing to and fro, the falling trees of the woodmen, the hammers of meny carpeoters, interspersed with the sharp explosion of giant powder from the surrounding hills, and within a short distence may he seen a hundred men busily at work carrying on their different vocations of life. Such is Mill City, El Dorado county. It reminds one of the early days of Virginia, or "the days of '49."

INYO.

Gold.—*Independent*, Nov. 11: The Messrs. Van Epps & Burden have received another chunk or two of gold, valued at $15 per ounce, and amounting to $800, from the Sacramento arastras. The mine, which is located in the White mountains, northwest of Bishop, at a depth of 100 ft shows a larger and much richer ledge than nearer the surface. It is only one of a great many equally promising properties which might bo profitably worked if the owners would only get to work at them.

Montezuma.—The Montezuma boys—superintendent, boss smelter, engineer and all the rest—are jubilant over the near completion of the works. The whistle has sounded already, and they expect to fire up for a short trial run within two weeks.

Mining Transfer.—Mr. Peter Laird hes sold the Blue Belle and Old Tom mines to Mr. Wm. A. Bolinger, who represents a company organized at Salt Lake. The properties are extensive and quite well developed silver mines, located near the summit of the White mountains, and more generally known as the Reed mine. The considerstion was $10,000, some of the cash having already been paid.

MONO.

Bodie.—*Free Press*, Nov. 14: The outlook for the Standard, Bodie and Oro is very flattering, and as the work progresses better ore is encountered. The Standard is extracting 1,400 tons a week, and the Bodie is shipping more than $40,000 per month. The Bodie Tunnel Co. is extracting good ore, and the Syndicate mill is running 12 hours a day. In a short time the Oro Co. will commence crushing ore. Altogether, the outlook for the coming winter is very encouraging.

Standard Con.—There was extracted and shipped to the mills during the past week 1,418 tons of ore. The bullion shipment was $20,344.86. The east crosscut, 1000 level, was run during the past week 13 ft; total length, 1,078 ft. There is no change in the character of the rock. The winze on south drift No. 2 has reached a depth of 92 ft; progress for the week, 11 ft. The vein measures 8 ft in width. The Cook upraise, which is now up 280 ft, shows a vein 0 ft wide. The stopes show no change.

Bodie Con.—There were 145 83 tons of ore hauled to the mill during the week ending on the 11th inst., and 118.604 tons were crushed. The average assay value of the pulp was $90.72 per ton, and that of the tailings was $17.60. The bullion shipment amounted to $10,168.34! The total length of the north and south drifts from winze No. 17, at the 670 level, is 183 ft. Thet of the drifts from the bottom of the winze is 143 ft. These workings and the stopes therefrom continue to yield rich ore. The pumps at the 1010 level are now in place, and all connections made, and they will be started up to-day. The new engines will be started next week.

Oro.—During the past week the 520 ft winze stope (south) yielded 20 carloads of ore. The vein in the roof is now 4 ft wide, of good milling character. The vein in the face of the south drift is 20 inches wide, of very good ore. It is widening out. Pumping is still necessary. Eight car-loads have been extracted during the week from below the 440 level. The ground is heavy, and it requires close timbering. As soon as 300 tons of ore is on the dump shipping to the Noonday mill will he commenced. The superintendent recommends that the 500 and 700 levels he connected, and prospecting be prosecuted on the 700 level.

Red Cloud Con.—During the past week the shaft wae sunk 0 ft, making its total depth 840 ft. The water le decreasing. Pumpe making less than 6½ strokes per minute.

Bodie Tunnel.—The ore formation continues to look well. Owing to repairs being made in the machinery, only five stamps were running during a portion of last week. Everything is in order at present, and the usual amount of ore is being crushed.

North Noonday.—The joint incline is 277 ft below the 515 level. The north drift, 325 incline level, is 102 ft in length; progress for week, 15 ft. Tho vein is very large. The drift is being run partly in the footwall and partly in the vein.

Noonday.—The south drift, 325 inclioe level, is 293 ft in length, 12 ft being the distance run during the past week. The joint iocline is now 377 feet below the 512 level. The mill is running steadily.

Bulwer Con.—The south drift from the west crosscut, 700 level, is in 256 ft; progress during the past week, 15 ft. The rock is hard, and shows some seams of ore.

NEVADA.

East New York.—Placer *Times*, Nov. 11: Sunday, Messrs. L. P. St. Clair, Wm. Trathen and Charles Harvey, owners of the East New York drift mine, on Steep Hollow, Nevada county, brought $3,700 worth of gold to town, and sold it at W. & P. Nicholls' bank. This was one of the finest lots of gold we have ever seen, there being many fine nuggets worth all the way from one to ten or twelve dollars. The East New York mine is on the main drift channel, and adjoins the famous Swamp Angel drift mine, from which so much gold was taken some years ago. The clean-up was after a run of 20 days. About 25 men are employed in the East New York, the larger portion being Chinamen. This is tho first clean up of importance, as the mine is now only fairly opened. The gravel looks well, and the owners expect to take out big pay the next year.

PLACER.

A Splendid Property.—Placer *Herald*, Nov. 11: The Morning Star mine, a few miles below Ophir, owned by the Hopkins and Reardons, is proving one of the best leade in this part of the country. These boys have been working it for about four years, and have taken out sufficient to pay all expenses, fit up a neat little mill, and put the mine in good shape. They are down on the main shaft 230 ft, and in the very bottom the ledge is two ft and a half thick, and the rock looks remarkably well. They have drifts run in from the bottom, and in these the ore also looks fine. Their last crushing yielded 3½ ounces to the ton. They have a new engine for hoisting purposes just completed at Taylor's foundry, Grass Valley, which they expect to have here and up in a week or two, and which will greatly facilitate their work. Five hundred feet north of the main works they are sinking another shaft, which is down 150 ft, and in which the rock also prospects well. The ledge here is from two to four ft thick, and their last crushing from this shaft went $18 75 per ton. They have, in short, a splendid property. They are hard working and clever gentlemen, and well deserve the success that is theirs.

Activity at Hotaling.—Under the direction of the new superintendent, Mr. U. Seeley, the work of reconstructing the buildings at the Iron mine is being crowded ahead as fast as the weather will permit. Quite a large force of carpenters and other men are employed there, and the place begins to assume its wonted activity. Since the fire a large amount of coal has been burnt and hauled to the furnace, to be ready when the works are again completed. The furnace will be reconetructed on an improved plan, whereby it is calculated the same amount of iron can be made with much less fuel. Mr. E. W. Cowles, who has been with the company since soon after it started operations, still retains his positiou as chief clerk, and he seems to be emphatically the right man in the right place. All here have reason to be gratified that the company has determined to rebuild on the site of the old works, and all hope its energy and courage may be rewarded by success.

PLUMAS.

Crescent Mine.—Greenville *Bulletin*, Nov. 11: The work on the mill is being pushed ahead rapidly. The water wheel is already in place, a large portion of the water pipe is completed, and as many men are at work on the remainder as can be conveniently employed. The car-

penters have got the building fully repaired without, and on the inside new floor has been laid in front of the batteries, the sluices and aprons are about finished, and two or three days' work will finish all the small part of the machinery. Nearly all the storage room is filled with ore, and some idea of the quality of the rock may be formed from this fact: On Monday we picked up a hammer, and, going to the rock pile, smashed up a number of pieces taken at random. These showed very rich in free gold; any estimate of the assay value, made by good judges of ore, would sound extravagant. As many specimens as could conveniently be carried were brought away, and can be seen at this office.

TAYLOR-PLUMAS MINE.—The very stormy weather of the past week has hindered anything being done toward building at the Taylor-Plumas. The arrangements for water for motive power have not yet been completed, but assurance is given by both Mr. Bransford and the Water Company that this matter will be definitely settled in a few days. Mr. Bransford intends to increase the working force in the mine, and push all work vigorously.

MINING BOOM.—Plumas *National*, Nov. 11. Considerable activity has recently been developed in the mining line in the neighborhood of the 20-Mile House, and a large section of mining ground has been located. The "boom," we are told, has been caused by predictions of a "dowser," or a man who claims to locate rich mineral ground by means of a "mineral rod." While we put very little faith in that style of prospecting, we are glad that the work is going on, as there are many substantial reasons for believing that some valuable claims will be opened, and a good mining district started up. Many old miners speak of the gravel beds there in flattering terms, and, as "the dowser" can bring men of means to develop them, he will prove a benefactor to that section of country.

SAN BERNARDINO.

BLACKFOOT.—Calico *Print*, Nov. 11: Harry Clay, who has been working for an interest in the Blackfoot mine in East Calico, belonging to Taggart and Joiner, struck a rich body of ore in the mine, it bearing permanence. The prospect is said to be one of about the best in East Calico district.

SALE.—Jerome Coldren and E. C. Linder have sold to J. A. E. Jordan their one-half interest in the Twin Sister mine, located at the east end of the Waterman range of mountains, for the sum of $2,000. The boys have put on white shirts, and are looking around for a location to start a national bank.

SNOW BIRD.—The Snow Bird mine, under the superintendence of Mr. Sinclair, is being worked systematically. Five men are at work sacking ore which assays from $134 to $2,000 to the ton. It will be shipped to the Oro Grande mill.

EAST CALICO ITEMS.—They are sacking ore at the Cuba No. 1 for shipment. F. M. Neill is opening up the Taggart mine. It is looking first-rate. The Blackfoot mine, owned by Taggart and Joiner, is being developed. It shows high-grade ore and the vein widening. Mr. Roberts is opening up the Bell mine, one of Taggart and Joiner's. They are getting good assays. R. B. Johnson, from Fish Pond, is working on the Sam Houston No. 3. Some assays from this claim go as high as $1,071 to the ton. The prospect is fine.

SIERRA.

PROSPECT.—*Quantin Messenger*, Nov. 11: The 1001 Gravel M. Co., Sierra City, obtained a good prospect this week. Blue Gravel Co. are taking out nice looking washed gravel with smooth bowlders. Mining stock is still rising in that rich mineral region.....Hamilton Smith, Jr., President of the Miners' Association, was in town last Sunday from the Ruby mine. They took out $1,200 last week.....The encouraging report comes over the ridge that the Ruby Co. are taking out a thousand dollars a week.

NEVADA.

WASHOE DISTRICT.

UNION SHAFT.—*Enterprise*, Nov. 11: Are enlarging the 1000 tank station, and making the usual repairs.

CON. VIRGINIA.—On the 2700 level the Joint California southeast drift has been advanced 16 ft.

MEXICAN.—The joint Ophir winze has been sunk 10 ft. The northwest drift has been extended 14 ft.

SIERRA NEVADA.—Are cutting out a drain in the main lateral drift. West crosscut No. 1 on the 2700 level has been extended 22 ft.

CALIFORNIA.—On the 2700 level the Joint Con. Virginia southeast drift has been advanced 16 ft. Extracting ore from the old croppings.

UNION CON.—Extracting ore from the south drift on the 2600 level. The main south drift on the 2900 level has been extended 20 ft. During the week 102 tons of ore have been extracted from the 2600 level.

UPPER.—The joint Mexican winze below the 2000 level has been sunk 10 ft. The main south lateral drift has been extended 7 ft and completed cutting down. During the week 23 tons of ore have been extracted from the croppings Bullion to the value of $11,895.37 was shipped last night.

CHOLLAR.—During the past week the drift south on the 2600 level has been carried forward 50 ft. The material through which this advance has been made consists of clay, porphyry and stringers of quartz. The quartz has an encouraging appearance and carries a small amount of precious metal, about $5 per ton by assay. On the morning of Monday last, in preparing for a blast, the drill cut a stream of water which gave a quantity of 3 miners' inches. The heated water made it necessary to cut a drain for the purpose of confining it, which caused delay and retarded drifting. Since striking the water the course of the drift has been changed from due south to south 16 degrees east, to avoid any further influx of water at this time.

YELLOW JACKET.—The water in the mine has risen 12 inches since the last weekly report, making it stand about 1,150 ft on the 3000 level station. At the Winters shaft we are extracting about 35 tons of ore per day from the 24, 34, 500 and 6th levels. The 6th level, 121 ft south of the shaft, worked in October yielded $23,157.72, or about $20.65 per ton. On the Sagebrush level the north lateral drift is in a distance of 490 ft from the switch, and continues in quartz containing some good ore.

COLUMBUS DISTRICT.

MOUNT DIABLO.—*True Fissure*, Nov. 11: The east drift from winze No. 1 is in 23 ft, and shows a 2-ft ledge of low-grade ore. Winze No. 2 is down 65 ft, and is showing a strong ledge of low-grade quartz in the bottom, with spots of ore of good grade. The west drift from the north crosscut, west of the shaft on the 3d level, is in 49 ft, and it shows 8 inches of $65 ore. The east intermediate, between the 2d and 3d levels, has developed a 3-ft ledge of $90 ore at a point nearly above winze No. 4. A body of ore 15 inches in width, and assaying $80 per ton, has been struck in the west drift from the north crosscut from the extreme east drift on the 1st level.

NORTHERN BELLE.—The main drift on the 5th shaft level has been advanced 23 ft during the week, the face showing a good width of sulphurets, giving low assays. From the vicinity of the shaft on this level a second crosscut has been started, which it is designed to run to the south to explore the footwall. The distance run to date is 16 ft. The crosscut from the main drift on the 3d shaft level is now in a total distance of 101 ft, having been extended 8 ft since the last report. The second shaft level is yielding as usual, and looks promising for the future. The stopes are looking well in the upraise from the first shaft level, and holding their width as the work upwards progresses. The usual amount of work is being done on the levels above the adit, with satisfactory results. The 9th and 10th levels present a promising appearance and continue their usual production. Everything is running smoothly in and about the mine, and the output of ore has been about 62 tons. Mill No. 2 is running steadily and doing good work. Shipments of bullion on November account, to the 9th inst., amount to $15,340.04.

COLUMBUS CON.—The usual good progress is being made in sinking the winze from the shaft level. Streaks of ore in a favorable formation are being encountered, and the outlook is very promising. The north crosscut is now in favorable ground and is showing low-grade ore in places. There is no change in the west drift, the face being in low-grade ore.

ESMERALDA DISTRICT.

WORK TO COMMENCE.—Esmeralda *Herald*, Nov. 11: The near completion of the mill at Gregory's flat has started claim owners to work, and some of our large mines will be started up shortly.

STAMPING AWAY.—The little mill started her stamps on Centennial ore Thursday morning. Owing to a scarcity of water the mill is only running on half time. Ball & Groth have 7 tons of rich ore at the mill to crush.

CRUSHING IN THIRTY DAYS.—Supt. McIntosh informs us that the Silver Hill mill, now being constructed on Gregory flat, will be crushing ore by the 10th of December. This is gratifying news to the people of this camp, and especially to those who have ore to crush.

SURVEY TO BE MADE.—J. S. Hiskey started a survey of the surface and underground workings of the Lewis Consolidated mining property, on Middle hill. This shows a confidence in the property by the owners. Supt. McIntosh says the property is improving all the time.

EUREKA DISTRICT.

ALBION BULLION SHIPMENT.—*Sentinel*, Nov. 11: A wagon load of bright-looking bullion passed down Ruby avenue yesterday from the Albion furnaces, the first we have noticed from these new works. This is ample and convincing proof that the "water jackets" are a success. When the bullion arrives in San Francisco it will no doubt be a pleasing and assuring sight to the stockholders of Albion, who have stuck to the mine through its hard and checkered career.

MINERAL HILL DISTRICT.

MILL BEING IMPROVED.—Eureka *Sentinel*, Nov. 11. The old mill at Mineral Hill, which, in the not long ago, was employed in pounding bullion out of $500 rock, and which has lain idle for some time, is being repaired, and will soon resume operations on a lot of low-grade ore. While the former good times may not come back entirely to the Hill, the busy thud of the old stamps will inspire confidence, and give the residents of our neighboring camp a new foothold.

PUEBLA DISTRICT.

FINE COPPER ORE.—*Silver State*, Nov. 14: J. C. Weir, who is developing copper mines in the Pueblo district, in this county, is in town. He brought in some samples of ore from his mines, which contain 60 % copper. He says there are three streaks, each a few inches wide, of such ore in the vein. L. Vary, of Bartlett creek, some 30 miles from Pueblo, says they have discovered some very fine copper mines in that vicinity. The mines are quite extensive, and the ore carries a high percentage of copper. The great trouble seems to be the remoteness of the district from the railroad, which makes the transportation of the ore very expensive.

TAYLOR DISTRICT.

BULLION.—Ward *Reflex*, Nov. 11: The Monitor M. Co. of Taylor district, shipped 10 bars of bullion last week valued at $3,868 16.

ARIZONA.

TOMBSTONE.—*Republican*, Nov. 11: One thing that ought to be urged upon claimants of prospects in Tombstone district is the more persistent prosecution of development work. It may be urged by such owners that they are too poor to do the same. In answer to this we will say that, from our knowledge of many of the prospects in this district, we believe that, if the owners will do their own work, they can take out ore sufficient to more than keep themselves in supplies, and for board, which, if a fact, and the work upon their claim shows any material improvement, it will be more to their advantage than it would for them to work for some one else, hoard their money and let their claims lay idle. We know that there are many locations now lying idle in this district that, were they in the northern part of the Territory, the owners would consider themselves rich, and would push development until they knew whether they had anything or not. Men in the north, who are so fortunate as to find a ledge carrying from 2 to 6 inches of ore, above $100 per ton, consider themselves fortunate, and go to work with a will to make a mine. There are probably 100 men in the Bradshaw mountains who are engaged in working small veins of gold quartz that pay all the way from $20 to $100 per ton. They work the ores in arastras, and cannot make anything less than $20 rock pay. All above that amount is profit. Certainly $75 and $100 silver ore will pay the owners of claims while doing development work, especially in a district like ours, where the facilities for working are so great. Besides, here the country rock is uniformly soft, and the veins of good size, which facilitates working. Had prospectors to contend with the hard granites, gneiss and quartzites, in which many of the northern mines abound, then they might well complain. If claim owners will cast their eyes over this district and see how many prospects have been sold in an undeveloped condition, at comparatively low figures, that have turned out well, they will certainly see cause why they should strive to develop before forcing their claims upon the market. Contention sold for $10,000, and has paid nearly $3,000,000 in dividends; Vizina, after rich ore was struck, sold for less than $10,000, and has paid $100,000 in dividends, besides paying for all its improvements; Ingersoll sold for $10 000, and has yielded not far from $200,000. This list might be extended, but that is not necessary. What we desire to do is to encourage claimants to do more work upon their properties before forcing them upon the market, as we believe it will be more to their interest so to do. In conclusion of this introduction we will state, as a fact, that we know of more good properties, right here in Tombstone district, than all we saw in our month's travel in central and northern Arizona, where mining is now having such a boom as it has not experienced for the last 10 years.

LYNX CREEK.—Cor. Prescott *Courier*, Nov. 11: We have 40 men in this camp. Buildings are going up everywhere. The machinery for the new smelter has arrived. Messrs. Brown & Cary, the gentlemen engaged to put up the smelter, have arrived here. Emsyn & Rowe are busy packing ore to this place from the Belle mine. Placer miners are jubilant and making plenty of money. I saw one man this morning, about 8 o'clock, who said he had made $2 by that time. Daniel Carlin, the brick contractor, has a large force of men employed making brick for the new smelter; about 30,000 are now in the kiln. The Belle mine looks fine and is turning out lots of ore. The probabilities are that we will have 200 men in camp by Christmas. We have laid out a townsite, and lots are selling at a high figure, and, if Prescott don't keep its weather eye open we will have a railroad first. Dr. Farnham, manager for a Chicago company, is rapidly erecting a 6-stamp mill.

COLORADO.

THE UNITED TUNNEL.—Georgetown *Courier*, Nov. 11: The United tunnel, on Kelso mountain, owned by W. F. Kelso and J. P. Davie, has now reached a length of over 300 ft, and shows in its breast a 4-inch vein of smelting ore that mills up into the thousands, and about a foot of concentrating ore. None of the ore that is now being taken out will be shipped before next spring, as the snow during the winter renders the expense of getting the ore down the mountain too expensive.

THE INDEPENDENCE.—For the past two months the Independence mine, East Argentine, has been producing a large amount of ore, which is being taken from stope No. 3, over the lower adit level, by Balotti & Co., lessees. The stope is 95 feet long, and shows an ore vein from 12 to 18 inches thick, composed of galena and decomposed ore, which at the last sale milled 73 ounces of silver to the ton. There are six men employed, who are taking out from 100 to 125 sacks per week. The property is owned by G. E. Clark, and at the present time is looking finely throughout.

CASCADE DISTRICT.—The ore and shaft house at the Financier lode has been completed, and sinking of the shaft has been resumed. It is now 28 ft deep, and shows an ore vein 14 inches wide that carries a large amount of silver glance. Fifty sacks were shipped on Tuesday to the Freeland smelter.....At the old Cecil lode, Mason & Co. have commenced to prospect, with the idea of taking a lease, and have already opened a vein of decomposed ore that carries native silver. The lode is owned by Harry Scoville, of Idaho Springs.....Dennis O'Fallen has sold one of his claims on Ute Creek for $2,000.

A TEST RUN.—*Register-Call*, Nov. 11: Last Saturday Mr. Speers made, at Black Hawk, a test run of 2 wagon loads of ore from the Kansas mine, property of the Quartz Hill Con. mining company, and as against a 5-stamp battery of that company at Nevadaville. The ore was mined from the same portion of the vein, and hoisted to the surface, one bucket being sent to the stamp mill and the other to Mr. Speers' amalgamating works, the entire lot being put through the amalgamating and crushing plan. The pan coppers were cleaned of the amalgam after the run and retorted, weighing 2 ounces and 11 pennyweights, gold. The same amount of mill dirt treated under stamps yielded 2 ounces and 6 pennyweights, the Speers process beating the mill 5 pennyweights, or 16 %. No concentrations are included in the run made, the yield being only from the gold amalgamated on the copper plates of the pan. Mr. Craven was present at Mr. Speers' works when the clean-up was made. From the above it would appear these works have much more merit than has generally been conceded them by many of our citizens who are interested in mining and milling.

GOLD SHIPMENTS.—The following amount of gold bullion has been shipped East this week by the banks: First National bank, $12,600; Rocky Mountain National bank, $8,000; Hanington & Mellor, $3,500; total, $24,060; total so far this month, $41,400.

GOLD DIRT ITEMS.—Col. John Q. A. Rollins was over last evening from Rollinsville. He furnishes us with the following news items from independent district and vicinity: The Red Jine company will be in readiness to start the new air compressors and power drills some time next week. Connection has been made from the west tunnel level of the Perigo mine with the shaft west, sunk by the company some years ago. The crevice of the Perigo does not diminish in width a particle, everything taken out either going to the smelter or the 10-stamp mill at Gold Dirt.....One of the bullion on Gold Dirt mountain is to be taken down and removed to Rollinsville, where it will be erected and used as a boarding house.....Freeso & Co.'s new stamp mill, in Lump gulch, will soon be ready to start up on ore from a group of mines in Central mining district. Col. Rollins predicts a regular boom for that section of Gilpin county next season.

IDAHO.

THE SILVER CHIEF.—Idaho *World*: This mine, which Jas. Monroe has a bond of, is the west extension of the great Bonner mine, owned by the Elmira Company, of New York. The celebrated Banner was located by Mr. Monroe in 1878, but having a number of ledges, he was compelled to sell this mine in order to develop the others. He realized $1,000, and to-day, after an expenditure of $6,000, the Elmira Company values it at a quarter of a million. The big tunnel just completed cuts their claim at a depth of 300 ft from the surface, and but 80 ft from Monroe's line, which is conclusive evidence that the Silver Chief is the same ledge as the Banner. And it is the opinion of many that it is the best ground of the two. Banner district can safely boast of the richest silver mine in Idaho.

MILL FOR DEADWOOD.—Ketchum *Keystone*, Nov. 4: Rev Ballard S. Dunn arrived the other day from an extended business trip through the districts of Custer and Lemhi counties. Mr. Dunn is managing some excellent properties out in Deadwood Basin, and has tapped one with a 200-ft tunnel, and sunk a 190-ft shaft on another claim, besides expending a great deal of other work on the surface. Developments made amply warrant the erecting of a quartz mill for the reduction of the ore on hand and in sight, and it is for the purpose of securing this same that Mr. Dunn leaves for the East soon. The mill will contain 10 stamps, and will be taken to its destination through this section. It has long been known that Deadwood contained valuable ore deposits, but no milling facilities have yet been given the camp. This enterprise will awaken a new era there.

VIENNA MACHINERY ALL IN.—A gentleman just down from the Sawtooth country gives the following facts concerning that locality: Galena is very quiet. Sawtooth is somewhat livelier, though greatly effected by the suspension of milling operations, and snow, which lies to the depth of two or three ft, closing out travel, ranchmen, prospectors, etc., for the winter. Vienna still goes on with the support of building enterprise of the immense quartz mill of the Vienna Company. The snow is about three ft in camp and three and one-half ft in the vicinity of the mines. As yet there is little ore at the mill, but it is probable that the teams now employed in hauling timbers to the mines will soon be put to hauling ore. The balance of the mill machinery reached its destination on Wednesday evening. About three and a half miles below Vienna the huge crusher, weighing 8,000 pounds, was accidentally tumbled over, and it was necessary to carry it the remaining distance on a sled drawn by 24 mules.

EAST FORK OF GERMANIA.—Idaho *Messenger*, Nov. 11: Two-thirds of the Germania, Sperling and Suderburge and one-half of the Hamburgh have been purchased by J. D. Wood, from Fred. Sperling, for the sum of $8,000, which is a very small part of the real value of these properties. Besides these Mr. Wood owns in the Great Eastern with Bob Moore and James Irving. The last named mine is situated about 1,500 ft from the Washington mine, in Washington Gulch, which is owned by Fisher & Boone, and considered one of the star mines of that superior camp. The Great Eastern ore, of saving grades, assays from 108 to 444 ounces. Two hands will work on it all winter. Few prospects show such a face of ore as this with no development.....Samuel Bergman is down from the head of the east fork of Salmon river, and confirms the universal report as to that country.....No camp of this extent, perhaps, on the coast, has so universally good showings in the face of its workings as has this portion of the Great Salmon region. When we visited it last spring the universality of goodness struck us as a little peculiar. The summer's labor has shown it better, and far more extensive than any one at that date had any idea of. New discoveries have been made in many places near the old, and the limits of the camp have been much extended—indeed we might almost say that new camps have been added to the old one. Even the East Fork of the East Fork is now showing wondrous bodies of ore, although there the grade is rather low, but such as, if utilized with a higher-grade camp that was near, would make both more useful. Besides, the probabilities are that high grades will be found in the midst of this lower grade region. If this should prove true in the future, no camp will be equal to the head of East Fork in that region.....The day is undoubted y near at hand when these camps will not only need a smelter of their own, but smelters.....Bergman informs us that 16 men will work in the Germania and Washington Basins during the winter, aside from what the Grand Pace shall conclude to put on. This is four times larger than last year, anyway. He says that, although just opening these mines, they have shipped 100 tons of ore this season going $200 per ton. There is, besides, some ore on the different dumps. Next year's output will, probably, be up well toward a hundred thousand, and if a smelter is erected, well up into the hundreds of thousands.

JORDAN CREEK PLACERS.—Idaho *Messenger*, Nov. 11: J. G. Morrison showed us a large amount of gold dust he had taken out of his Jordan Creek placers, and quite a number of rock specimens that were taken from the Washington ledge, which crosses Jordan at the placer grounds. One piece, taken from 100 ft depth, was remarkably fine—being literally filled with gold. The value of this gold, per ounce, is $13. It seemed like California and eastern Oregon in the days of gulch mining. The gold is what is termed coarse, many specimens being an ounce in weight, and some pure, without any rock, the weight of 6 to 7 ounces and as large as a fair-sized hen's egg. Such are fine pieces to pick up, and the sight of them made us old 52ers feel young again. Still we apprehend what lies in the ledges will prove by far the greater wealth. The Pilot, which connects with the Washington on the east, has 1,000 ft on the east side of Jordan creek—lying between Jordan and the Charles Dickens, and joins the Dickens on the west. This is also a well-defined vein—traceable on the surface to the common observer, and, undoubtedly, will prove to be, as it is estimated, a good, solid 4-foot vein, with enlargements according to depth. This would make an amount of quartz from the lower tunnel in the Charles Dickens, which is about 200 ft from the west end of the latter mine, that would be simply enormous, really in sight, as its peculiar situation between a mine that is opened and lying on an incline exposes the whole length and certainty of depth that far. The property will, we might, almost to a mathematical certainty, say, prove to be worth millions of money—and so easy to which to make an opening.

MONTANA.

NOTES.—Butte *Miner*, Nov. 11: The belt of leads discovered in the vicinity of Sheep mountain are believed to be a continuation of Barker and Montana mineral belt... Returns of assays from the Teton lode, in the Montana district, owned by Morrison & Stocking, have been received, and figure up $208 85 in silver and 27 % lead to the ton.....The returns of assays of ore from the Fitzpatrick lead, in the Montana district, which had been sent to the assay office at Helena, go $3,050 to the ton in silver.....The Barker district is assuming the proportions of a permanent and substantial mining camp very rapidly. The Benton *Record* says: The Wright & Edwards mine has 4 ft of solid ore, and it is keeping the roasters of the smelting company busy. For the last 14 or 15 days they have had a nice run of the finest bullion that the Clendenin M. & S. Co. has ever yet turned out... In the vicinity of Sterling, Madison county, several rich strikes have recently been made. Reel & Haggerty have struck a ledge 2 miles east of town, which assays $44 to the ton at a depth of 20 ft.....The Norwegian mine, in the same vicinity, has struck a 4-foot ledge on the 170 level, which produces, at the mill, $38 to the ton. A mill is being erected, and the mine will be worked to its full capacity.

NEW MEXICO.

KINGSTON.—Cor *New Southwest*, Nov. 11: I got into Lake Valley Saturday; found considerable change in the last few weeks. Old Town entirely gone and a new city of about 70 houses built just south of the mines, but the building boom is about over. The city looks dull, everybody is going or gone to Kingston. On the trail north towards Kingston the first camp is Wett's Boys, 10 miles out on the Sierra Blanca; some good looking prospects there. The boys are on a sale, but I cannot get any particulars. One mile farther north, on a branch of the same creek, is another camp, where Sheduen has some men at work. Two miles north you cross Trujillo creek, where Col. Parker and others have some good prospects. Three miles farther north, on the South Percha, Gov. Stover and others, of Albuquerque, are running a tunnel to develop a group of mines. A steam saw mill is running just below them. Two miles north is Kingston, headquarters of the celebrated Percha district. I was rather surprised myself at the extent of this settlement. The town extends about a mile and a half along the creek; contains about 1,500 people and over 200 houses, principally board houses covered with canvas. The dust is about a foot deep. There are no churches, but about 30 saloons. Restaurants by the dozen. I noticed 2 hardware stores, 3 assay offices, 5 real estate offices, house and sign painter, contractor and builders. The principal mines in this vicinity are the Bullion King, owned by T. F. Chapman and others. They have shipped $64,000 out of a 70-ft shaft. Superior, owned by Col. Logan and others; they are working about 34 men. The Iron King is shut down at present, waiting for Mr. Richards, proprietor. The Illinois, handled by Col. Logan, is developing into a fine property.

OREGON.

NOTES.—Jacksonville *Times*, Nov. 12: The country is filling up with miners.....Most of the miners are ready for the winter's run.....Supt. Ennis, of the Sterling mines, says there is plenty of water and he will commence active work next week.....Eleven inches of snow fell last week along the line of Bybee & Co.'s ditch, near Waldo, but Supt. Hawkett expects to finish up the work and get ready in time for a full season's run.....The party who built Welch & Co.'s quartz mill arrived at Blackwell, from Portland, this week to put it in operation. Derickson & Co., of Horsehead, have a similar mill.....Messrs. Burrage and Pomeroy, of Portland and Oswego, who have been prospecting for iron ore in the hills in the vicinity of Rock Point and Gold Hill, are said to have found very rich and extensive deposits. We learn that the chances are favorable for a furnace being put up somewhere along Rogue river when the railroad is completed.....Our mining interests will, in all probability, receive an impetus before long. The hills are full of rich minerals of every kind, and all that is needed to make Jackson one of the foremost mining counties on the coast is capital. Already prospectors from abroad, and representing men of means, are making their way hither. Developments of an important character will be made, which will attract general attention, and then look out for a boom. Southern Oregon is destined to be a very rich and prosperous section

UTAH.

BEAVER CO.—Cor. Salt Lake *Tribune*, Nov. 11: Half way between Milford and Mineraville is the great Cave mine, being steadily worked. Its ores are sent to the Friaco smelter. This ore carries but little lead, and fluxes well with the ores from the Carbonate mine, of Frisco. From Mineraville to this place, a distance of 22 miles, the road is in the valley all the way. Here and there the valley widens out and has many acres of good grass lands, which have been taken up by ranchmen.

SALT LAKE NOTES.—*Tribune*, Nov. 14: Four smelters in the valley below the city are running up to their full capacity, and turning out large quantities of bullion..... The weather is all that could be desired, and the miners and farmers are making the best of it.....Mining men are coming in from the Wood River and other mining countries in Idaho, and other places, to spend the winter in Salt Lake.....The receipts of precious metals, reported by bankers of Salt Lake for the week ending November 9th, aggregates $8,870 86.....Many of the Wood River miners think they made a mistake in not shipping their ore to Salt Lake instead of permitting it to lie on the dumps all summer. It will be late next spring before is is marketed.....The ores being reduced at the smelters near this city run higher in lead than formerly, the present average being about 45%. This is partly attributable to the fact that miners are more careful in selecting their ores for shipment than formerly.....The new white lead works being erected by the Germania Co. will have a capacity of 3,000 tons per annum, which can be increased to 5,000 tons without enlarging their power or buildings. The product of refined lead by the company will aggregate 6,000 tons for the year 1882.....The Germania Smelting & Refining Co. are using Selectric lights, and have ordered another Brush plant for 16 more lights of 2,000 candle power each. These lights are to be used about the present works and the white lead works which they are erecting. The machinery will be here in about a month.

NOTES.—*Southern Utah Times*, Nov. 11: It is said that work will soon be resumed upon the North Horn Silver ground.....John Kemple has struck fine ore in his Kanarrah mine, in Star, at a depth of 175 ft.....The bullion output of Park City for 1883 will be between $4,000,000 and $5,000,000, or as much as produced in the entire Territory in 1879.

PARK CITY.—Salt Lake *Tribune*, Nov. 11: The engines for the Sampson mill are expected from the East in a few days.....The roads between the Park and Salt Lake City are reported in good shape. The stages are making regular trips.....The Crescent company is hauling ore as usual, but experience some difficulty on account of the mixed condition of the roads, part being covered with snow and the balance soft mud.

The Denver Exposition—No. 13.

[Editorial Correepondence].

From the brief general description of the Black Hills of Dakota, which we gave last week, the rsader may well snppose there is no exaggeration in calling this

The "Wonder Land"

Of the mining regions. They are literally a miniature representation of the vast aggregate of the minee of the continent. In variety of mineral resources, when extent of territory ie considered, the Black Hills are without a rival in the world. Surrounded on every side by level or rolling plains, through which they have have been puehed up hy forces from beneath, they constitute a psrfect and complete geological syetem, with esch snccessive formation fully exposed to scientific investigation and mineral exploration. The records of these formations are heautifully and faithfully shown on the npturned edges of the rocks themselves.

Commencing at the summit or center of the upthrow we have a protruding nucleus of upturned granite and metomorphic rocks, succeeded in every direction as we dsscend the slope by mica-echiets, slatee and quartzitee, of Archean time, each in its regnlar place. Passing theee we reach the encircling helts of later formations—lime, sandetone, etc., extending continuouely aronnd the "Hille," all arranged in the proper order of their formation, and all with a general dip from the center toward the plains beyond.

If one were to go out into the plains below the foot-hills of the eastern slope of the Rocky Mountains and excavate a circular opening to a depth equal to the hight of the Black Hills, and a diameter at the surface equal to that of their hase, he would have a perfect counterpart of the "Hills" themselves. Such an opening would be abont 50 miles in diameter, descending like the inner surface of an inverted cone to the depth of ahout 8,000 feet. But with all the lahor of such an excavation, the explorer would not have a hetter opportunity to stndy the geological formation than is presented hy this remarkahle upheaval. Within the limited area of these "Hills" are fonnd gold, silver, copper, iron, coal, mica, gypsum, graphite, aehestos, salt and petroleum. These minerals all occur in workahle quantitiee, and specimens of each one were ehown at the Denver Exposition. It is eaid to he poseihle to visit all these various mineral deposits on a good horse within 12 honrs. So far, only the gold, silver and mica mines and the salt springs have been practically explored. But we are assnred that the time will eventually come when all theee deposits will hecome important sources of wealth, eepecially the mines of copper, coal and iron.

Rapid City,

Located on Rapid river, the largest and central stream of the conntry, holds a central position, heing abont half way between Deadwood and Cueter. The Rapid river never carries lese than 3,000 inches of water, and its volume ordinarily would measure from 5,000 to 7,000 inches. It is the only watercourse of the hills that never fails—that flows continnously from source to mouth through the dryest seasons; and it cuts through the metaliferons formations and crossee the great mineral fissuree, which trend from the northweet to the southeaet, at their widest extent. All the Black Hills' currents flow from west to east. Ahout 40 miles of the Rapid, including the Little Rapid and Castle creek, its principsl trihntaries, are auriferous channels; and then from ite debouchure from the mountains to where it emptiee into the south fork of the Cheyenne river, a distance of ahout 50 miles, it flows through a deep alluvial soil of surprising fertility, enriched hy washings from the vast gypsnm reefs above. Rapin City is beautifully eitnated on the eastern foothills, in a position to command both the farming and mininy trade, and is one of the most progressive young cities of the Northwest. It now has a population of nearly 2,000, which is rapidly increasing, having advanced from 500 to the present figures within the last two years. There is now a closely-connected chain of farms 20 miles long etretching from Rapid City down toward the Cheyenne river.

Though the water of the Rapid is destined to be like that of the Sacramento, which hae heen for so many years made mnddy hy placer mining operations above, the citizens of Rapid City will never snffer from lack of clear, pure water. About three miles above the town ie a group of some of the largest freshwater springs in the world, the combined currents flowing from them being adequate to supplying a city of 100,000 inhabitante; and theee springs are high enough above the eite of the town to insure throwing the water by hydraulic pressure over the higheet buildings.

The Black Hille region claims to have

The Largest Gold Quartz Mining Company

And the most extensive hydranlic mine in the world. The quartz mining company is the one already alluded to in our last letter, the Homestake and associated mines, owned principally by J. B. Haggin, Lloyd Tevis and Geo. Hearet, of this city, and which is now rnnning 580 stamps, under one management, and still constantly extending its working facilities. These compriee the leading minee in Lawrence, the moet northern county of the hills region. The deepest ehaft thus far sunk is 450 ft. There are quite a nnmher of other mining properties in this and other localities, which are well worthy of mention, had we time or space. We can merely add that there are indications of permanency ahont these mines which fully warrant the assumption that the futnre of the Black Hills country, as a mining region, is decidedly hopeful. The mines are of prodigions width, and their great value does not depend so mnch upon the richness of their ores as upon the faot that they are practically inexhaustihle, of uniform yield, and easily extracted. The ore is quite essily crnshed, two tons per day to the etamp heing about a fair average, while the appliances for handling it are generslly the most economical that can he introdnced.

The Gold and Silver Production of the Hills.

Notwithetanding the fact that the general average of the ores of this region is very low grade, the further faot that many hundreds of tons have been hanled 300 miles by ox teams, and then 433 miles further by railroad to Omaha, with a handsome profit to the owners, ought to dispel the idea that there are no high-grade ores in the Black Hills. An aggregate of ahont $11,000,000 has already been produced here, which ie a very remarkahle output for so limited an area and so short a time for development. The last Mint report gives the yield of 1881, $3,994,842. But as railroads are heing rapidly conetructed, water ditches provided for the placers, additional stamps for quartz and smelters for copper, silver and lead, the yield in the futnre mnst he rapidly augmented.

The Placers of the Black Hills

Have not as yet heen worked to anything like their full extent, on account of the lack of ditch facilities for obtaining water, either in quantity or at a proper elevation. Capitsl, however, is now going in, which will soon supply this need. The Harney Hydraulic Co., of Custer county, will soon he in possession of some 400 acres of grornd, with valuahle and sufficient water rights to work the same. Some of this ground is known to he extraordinarily rich for hydraulic working. Many other extensive hydraulic operations are under way or projected. One very large operation is in progress for turning Rapid river from its hed. In many cases gravel ie carted quite a distance to he worked. The Estrella del Monte, already alluded to, bide fair to hecome a valuable property, although not yet having completed its extenaive syetem of flumes and ditches; it has yet to show what may be its financial results. Judge Maguire furnishee ns the following particulars in regard to this company: "It owns and ontrols the entire currents of Castle creek and the main Rapid throngh a chain of five connected water rights, and thus holds the keys to the tressures imhedded in thousands of acres of placer bar ground which ie eo rich that miners have heen doing well during the last six years hauling gravel long dietances from these hars down to water for waehing. They will all he covered hy the Estrella del Monte Co.'s flumes and ditches, so they csn be worked off under a hydraulic presenre. It is estimated that the company's grounds cannot he exhausted in 40 years' working, with work in steady progress along the five divisions of flumes and ditches. As yet hydranlice have only been pnt in operation on the Castle creek division, the resnlts being altogether satisfactory; but construotion work is heing vigorously pushed at all points, and it is helieved hydraulics will hy next season he in operation all along the Rapid and Castle creek. Such a resnlt must swell the gold yield of the Black Hills very largely."

Silver Mining in the Black Hills.

Thus far hut little has been done in the Black Hills in the way of eilver mining, the yield, all told, having been only ahont $150,000; hut the promise ie fair for that country yet hecoming famous for its silver production. It will probahly take the same course that Colorado, Montana and Idaho have taken—hecome famous for silver production long after eetahlishing its fame for a gold producing region. The elates, granites and porphyries of the Hille are walled in on all sidee by a lime formation—as already described in our last letter. Thie formation is rich in silver carhonates, as "float," which has heen found at almost all points along the line of junction of the lime and the other formations. But comparatively little prospecting hae heretofore heen done for silver. Some very rich argentiferous ores from the Hills were placed on exhibition; and we are led to believe, from the facts given us by Judge Maguire, that the Black Hills hid fair to take high rank in the near future in silver production.

Copper Ores.

Very rich copper ores were also on exhibition, the assays showing a good percentage of eilver. It is said one of the Black Hills oopper mines—the Wall Street, in the western part of Pennington conrty—will soon be put in progress of thorough development by a New York company, and ench results are anticipated as will at once give the Black Hille prominence for oopper production. The Wall Street is said to he a vein of very great extent, the ore bodies heing 25 feet wide on the average, and it can he traced by bold croppings throughout its entire linear extent of 1,500 feet. The great Blue Lead, also in Pennington county—said to he milee in longitudinal extent—carries copper, silver and gold. We are assnred the ore bodiee in places on the great Blue Lead are over 100 feet acrose; but, owing to their refractory character, the owners of mines on this enormous fiseure have difficulty in securing capital for development. With the Wall Street ores, however, it is different; they carry a sufficiency of fluxing material, and oan be cheaply and easily reduced.

Magnetic and Hematite Iron Ores,

Of grest purity, are found in vast hodies on the western side of the Black Hills; and in close proximity there are immense seams of excellent hituminous coal. Railroad communication will not fail to mske these coal and iron fields sources of great wealth.

The Saline Springs

Are ahout 45 miles in a sonthwesterly direction from Dsadwood. The salt now manufactured at these springs is bsing ueed in all the Hill towns and eettlements. The natural capacity of the springs are said to he almost unlimited; they could, with adequate manufacturing facilities, and in the not distant future most likely will, eupply all of Eastern Montana and Western Dakota with salt. There are also

Natural Petroleum Wells

Of mnch promise on the head of Castle creek. The Homestake and other companies use the crude petroleum obtained at the wells for lubricating purposes. Refining worke will in time be erected, when the hille will he supplied with illuminating material of home prodnction.

Black Hills Mica

Is now holding a prominent place in the general markets for this peculiar and ueeful mineral. The varieties found embrace all kinds—wine-tinted, white, green and snuff-colored. It splits freely, and the various shades are all perfectly traneparent when split into plates thin enough for use in stoves. The Black Hills micas stand the first test equal to the best Siherian, North Carolina and New Hampehire micas, and it ie often taken out in unfractured hlocke that will square six inches and upwards. The Anglo American Company of Boeton ie now employing a large nnmher of men in the Black Hille mica mines, and its success has encouraged the organization of a nnmber of other etrong companies to develop mics property there. It is claimed the Black Hills will he the chief source of supply for mica through the future. The blooks are found in white feldspar formations in Pennington and Custer counties, stndding the feldspar usnally in a perpsndicular position, as raisins do a plum pudding.

Marble, Gypsum, Timbsr, Etc.

Asbestos, marhle, gypsum and excellent hnilding stones abound in the Black Hills, hut as yet have attracted hut iittle attention.

All the elevations are covered with white and red pine of good sizs, to he manufactnred into lumher, while the hard woods, oak, ash and elm, grow on the foothills and in the lower valleye. There are heantiful grassy parks all through the mountaine, some hnndreds of acres in extent, and msny of them are now being succesefully farmed. Bountiful crops of grain and vegetahlee are raised in the very heart of the Black Hills.

San Francisco Merchante and Capitalists.

San Francisco capitalists have alreedy found the Black Hills mines to he a locality favorable for the profitahle investment of capital, while her merchants are rapidly extending their trade to this wonderfully rich region, with satisfactory resulte to themselves and patrons, and should be awake to their interests in future developments in that direotion. The Black Hills are just starting on their career of progress and proeperity. When railroads ehall have heen extended there, the population will increase with amazing rapidity, and the world will he astoniehed at the developements of wealth and enterprise that will he eure to result. The country, all the way northwestward from the Black Hills, along the eastern hase of the Big Horn mountaius to Bozeman, in Montana, possesees varied wealth, embraces valuable mineral, farmiog and grazing lands, and is destinsd at no distant day to he thickly populated. Snch an inviting field for railroad conetrnction will not long remain unoccupied. The Black Hills will not much longer hold a poeition of isolation. A region posseesed of such vast and varied natural wealth cannot he kept in the background. She is bound to come to the front, and the merchants of San Francisco would do well to follow the example of her mining capitaliets—secnre a permanent footing there, and share the fruits of future developments.

Dakota's Displav.

The display of Dakots, from the fact that more than 300 miles of hauling by teams was involved, did not compare favorably with other localities. Another reason for euch inferiority grew out of the fact that the low-grade ores would not compare favorably, and to show them in qnantity wae altogether too expensive an nndertaking. The eamples sent were calculated to merely give a hint of the nature and variety of her mineral products. While most mines sent large epecimens of low-grade ores to show, hy their eize, the width of their veins, such an exhihit wae impossihle for Dakota, for who would have ventnred to engineer an nndertaking to show the width of the veine, the etopee of some of which are worked from 100 to 150 ft. across. It would have been ahout as easy to have moved the exhibition to the mine, as euch a section from the mino to Denver. Only about 100 sample epecimens were sent, including gold, silver, copper, lead, coal, asbestos, salt and gypsum, grnnd raw and calcined. One of the moet useful and practical leeeone taught the mining public hy Dakota is the fact that fortunee may be made from six-dollar rock, miued more than 300 miles from railroad communication with their supplies. Our space at thie time will not admit of the proof and partioulars of this lesson, hut we propoee to give it editorisily in fnll in some future issue of the PRESS. W. B. EWER.

Working Copper Ores at Spenceville.

From a letter in the Grass Valley *Tidings* we make the following extracts:

The Spenceville Copper Mining Company have 43 acrss of copper-hsaring ground, and 100 acres of adjoining land, which was hought for the timber. There is a hoieting works, mill, roasting-sheds and leaching-vats on the ground, and they cover several acres.

On going aronnd with Mr. Ellis, the first place we csme to was the mine proper, which ie simply an immense opening in the ground covering ahout one-half of an acre, and about 80 feet deep. It has an incline running down into it, hy which the ore is hoieted to the surface. Standing on the hrink of this opening and looking down, we could see the men at work, some drilling, othsrs filling and running the cars to the incline to he hoisted to the surface.

The ore is found in a sort of chloritic slate and iron pyrites which follow the ledge all around. The ore itself is a fine-grained pyrite, with a grayieh color, and it is well suited hy its sulphur and low copper contents, as well se hy its properties, for heap roasting. In heap roasting the ore is hand-broken hy Chinsmen into small lumps before heing hoieted to the surface. From the landing on the surface it is run out on long tracks under sheds, dumped around a loose brick flue, and on a few sticks of wood formed in the shape of a V, which runs to the flues to give a draught. Layers of brush are put on at intervals through the pile. The smaller lumps are placed in the core of the heap, tho larger lumps thrown upon them, and 40 tons of tank residues thrown over all, to exclude excsee of air; 500 lbs. of salt is then distributed through the pile, and it is then set afire. After well alight the draught-holee are closed up and the pile ie left to burn, which it does for eix months. At the expiration of that time the pile ie hroken into and sorted, the imperfectly roastsd ore is returned to a fresh roast-heap, and the rest trammed to the

Leach-Vats.

These are 50 in number, 10 having heen recently added. The first 40 are four feet by six feet and four feet deep, the remaining 10 twice as large. Ahout two tons of hurnt ore is put in the small vats (twice as much in the larger ones), half the vats being filled at one time, and then enough cold water is turned in to cover the ore. Steam is then injected heneath the ore, thus hoiling the water. After boiling for some time the steam is turned off and the water allowed to go cold. The water, which after the boiling process turns to a dark red color, ie then drawn off. This water carries the copper in a state of solution. The ore is then boiled a second time, after which the tank residues are thrown out and water kept sprinkling over them. Thie water collects the copper still left in the resi-dues, and is then run into a reservoir, and from the reservoirs still further on into settling tanks, previous to

Precipitation

And is then conducted through a system of hoxes filled with scrap iron, thus precipitating the copper.

The richer copper liquors which have heen drawn from the tanks are not allowed to run in with that which comes from the dump heape. This liquor is also run into settling tanks and from them pumped into four large barrels, mounted horrizontally on friction rollers, to which a very elow motion is given. Theee hsrrele are 18 ft. long and six feet six inches deep outeide measure. Thoy are huilt very strongly and are water tight, 10 tone of scrap iron is always kept in each of these barrele, which are refilled six times daily, oomplete precipitation heing effected in less than four hours. Each barrel is provided with two safety valves, inserted in the heade which open automatically to allow the escape of gas and steam. The precipitation of the copper in the barrele form copper cement. This cement is discharged from the barrele on to screens which hold any lumps of scrap iron which may be discharged with the cement. It is then dried hy steam, after which it is conveyed into another tank, left to cool, and then placed in bags ready for shipment as copper cement. The huilding in which the liquor ie treated is the mill part of the property, from which they send out 42 tons monthly of an average of 85% of copper cement, this heing the average yield of the mine.

There are 23 white men and 40 Chinamen employed at the mine and the mill. There are also several wood choppere, etc., on the company's pay-roll. Eight month'e supply of ore is alwaye kept on hand, there now heing 12,000 tons roasting. The mine is now paying regular monthly dividends, and everything argues well for the continuance of the same.

PURE HYDROCHLORIC ACID.—Giudice prepares the pure acid, whether gas or liqnid for experimental purposes, hy the action of sulphnric acid on eodium chloride, bnt adds to the former eome oxidizing substances like potaseium bichromate or permanganate, or the black oxide of manganese. The gas ie passed through mercury, contained in a Liehig's potash bulb, or other suitable apparatus, before it is passed into water or ueed.

CONSUMPTION OF COAL IN LONDON.—The total coal hronght into the Metropolitan area in 1881 amounted to 10,563,948 tons; of this 6,754,492 tons were conveyed hy railway and canal, 3,809,456 tone being conveyed hy eea. The total in the previous year heing 9,915,488 tons.

The Secret of Success.

It is well known that both France and England produce much more to the acre of cereal and vegetable products than is realized from the same area in the United States. The estimate for France is fifty per cent. more, and a much larger per cent. for England. Why is this? How is it that English farmers can so exceed our own—especially when we consider the many centuries during which English farms have been under cultivation. in excess of those of this country?

The secret of their success is due to greater care which they exercise in raising and selecting seeds and in all the various processes of cultivation. American farmers appear to think that anything will do for seed; that drainage is of but little account; that heavy manuring will damage the soil and "burn out" the crops; that deep plowing is hurtful and careful cultivation will not pay for the extra labor. In California a farmer has been heard to boast of a new and valuable labor saving process which he had introduced on his farm in turning a small stream through his stable and stock-yard by which he was enabled to "sluice out" the manure and get rid of it much cheaper than by use of the shovel and cart! It is full time that such folly was done away with; it has had its day. Let our farmers adopt the more reasonable plan of feeding the land, that it in turn may feed the crops. When that is done we shall have no more of worn-out lands, and our average wheat crop will go up to the English standard of thirty or thirty-five bushels to the acre, instead of the present yield of only fifteen.

No one quality is more needed by the average Californian than carefulness. Our people waste enough to support comfortably another population equal to the present one. This wastefulness which is manifested in almost everything is what keeps the majority of our people comparatively poor. We ought to be the most prosperous people on the globe, and the reason we are not so is because of the endless little leaks which we certainly permit if we do not indeed encourage.

To go back in our remarks to the farm—Manure lost is money lost; and yet we go on throwing it away, or at least the great bulk of it, year after year, as though it was of no value. The Chinese and many of the Italian gardeners are exceptions to the rule, and they realize from an acre of ground fully double the value which an average American will obtain.

Take the case of farm produce; the past month tells a story of carelessness which is absolutely astonishing to a resident of even the Atlantic States. Take our stock ranges, innocent almost entirely of anything in the shape of shelter from winter rains and cold. In addition to a large percentage of actual loss from exposure, those that survive require about double the amount of food which would be needed for stock properly sheltered. The animals are compelled to generate the heat from food, which is radiated from their bodies by lack of shelter. That much food is lost for all practical purposes.

In regard to our grain crops, there is not one farm or ranch in twenty which produces anything like the yield which might be derived from a more careful cultivation and proper preparation of the soil. There is also much unnecessary waste in harvesting.

Then, again, there is great carelessness and loss in and about the farmer's home. His wagons and farm tools are too often allowed to needlessly deteriorate by reason of exposure to the weather. The same carelessness is quite too often seen in the house and especially in the kitchen. The custom of driving two horses instead of one in a single buggy is also oftentimes a reckless waste of horse and horseflesh. Shelterless homes, *sans* trees, *sans* shrubbery, *sans* garden, *sans* paint or whitewash are too often the rule, where cosy cottages, shaded with trees and covered with vines and flowers might beautify the landscape and add immensely to the pleasure and prosperity of our farming community. A well kept house and a well tilled farm is a comfortable living and a fair competence to any man; while on the other hand slackness and carelessness about the house and farm is an almost sure cause of poverty, which is too often the parent of wretchedness, if not of crime.

Preparing Wood Pulp.—A pulp manufactory in Somerset county, Pa., consuming spruce and hemlock timber, instead of chopping down trees and sawing them up, in order to get the wood into the pulp mill, blows them to splinters with dynamite. An eye witness thus describes the process: "A fine large spruce was selected, and a hole was driven in about 10 inches, the chips were removed, and a dynamite cartridge was inserted. The dynamite comes in sticks like a candle, and resembles moist brown sugar. A fuse was attached, and the men sought a place of safety. In a few seconds there was a mighty roar, and the great tree was lifted up in the air about 10 feet, and then with a swoop and a crash it came to the earth, splintered half way up the trunk. Dynamite is not cheap, but taking into consideration the time, labor, and wear and tear of tools saved, is not as expensive as might be supposed." It is questionable, however, whether some standing timber not demanded by the manufactory is not seriously injured by this process.

Cotton Seed Oil.—A factory has been opened at New Orleans to make illuminating and lubricating oil out of cotton seed oil.

Useful Information.

Are Toads Poisonous?

In answer to this query, propounded by Mr. Herbert Brown in a recent number of *Knowledge*, a decided affirmative may be returned. The toad *is* venomous, though not in the way that is implied by the general acceptation of that term as is commonly believed. Nothing can be more harmless than the bite of a common toad—if it can be said to bite, for it has no teeth. But the glands contained in the papillæ and rugosities of the skin covering the back, secrete a milky, highly acrid fluid, which is exuded profusely on irritation. Indeed, if it were not for this poisonous secretion, the poor toad would fall an easy victim to many enemies, having neither the agility of the frog or lizard to enable it to make its escape, nor the teeth and claws of other reptiles wherewith to defend itself. Cats, which are eager hunters of frogs for food, spit and foam at the mouth when they pick up the wrong batrachian by mistake; frog-eating snakes, too, detect the difference, and will not take toads as a rule. When a snake, greatly pressed by hunger, swallows one, it usually rejects it again immediately afterward, and not unfrequently dies. Those frogs which prey upon their own kind (as most frogs do) despise their ugly relative from an alimentary point of view; and, curiously enough, certain toads which devour frogs share the same antipathy to their race. Except with very small animals the poison appears to act rather as a local irritant than a toxic agent; it has no effect upon the sound skin, but will cause any abraded surface to inflame to extensive ulceration, while great pain results from its application to the internal mucus membrance.

Any one who can overcome his repugnance to the creature sufficiently to put his lips or tongue against the skin of an angry toad will experience an intensely acrid taste; he should shut his eyes in making such an experiment, as the glands sometimes emit their secretion in a jet. Mr. Frank Buckland quotes a case which occurred in Oxfordshire, where a drunken brute hit a toad's head off. Happily, his teeth went right through these glands, and his mouth and throat immediately became swollen and inflamed to such an extent that his life was in jeopardy for some hours. These characteristics are much more strongly marked in many of the tropical toads. My giant toads used to swelter venom when they were taken in the hands in such abundance that it would pour off their backs and drip from them, before they became tame; and I was thus enabled to collect a large amount. This species feeds on rats, and it is possible that this copious exudation may serve to prevent their prey from biting them when seized by the leg or otherwise awkwardly caught. I once put a "criho" snake (*Dromicus fugitivus*) into a box with three of these toads for a single night, for lack of other accommodation; it was a fine, active specimen, five or six feet long, and its movements during the night so disturbed them that in the morning I found the floor of the box all awash with fluid. The snake was lying on its back, apparently dead; and, though it recovered somewhat on being plunged into a bath, it survived only a few days.—*Arthur Straddling in Knowledge.*

Sewing Machines in Germany.—Germany is producing sewing machines more cheaply than any other country on the globe, and the quality of German machines has been greatly improved in the last ten years. German machines are provided with all the modern improvements, such as loose pulley, automatic bobbin winder, shuttle ejector, tension, liberator, etc.; while most of the old American companies refuse to introduce those essential improvements on their machines. In consequence of this fact, German machines are very often preferred. For instance, the Wheeler and Wilson machines still have the bobbin winder on the end under the table. For this reason some dealers do not want them. German machines of the Singer pattern are sold in Berlin at from $10 to $12 wholesale, complete with all the improvements. A Berlin correspondent of the American *Sewing Machine Journal* says that the only way to introduce American machines in Germany is for American manufacturers to "branch out" as the Singer Company has done. The only competitor who has made himself felt by the German manufacturers is the general agent of this company, whose success is attributed to their method of disposing of machines in a way to create a demand among consumers, thus compelling local dealers to supply them.

Cement to Withstand Petroleum.—Gelatine (glue) mixed with glycerine forms a compound which can be liquified by heating, but which solidifies on cooling, and forms a tough, elastic solution, having somewhat the appearance and character of india rubber. This compound is entirely insoluble in petroleum or benzine, and any vessel coated or painted with it becomes impervious to these liquids.

Money Value of Science.—The Signal Service Office estimates that ships containing at least $13,000,000 of property, besides many lives, were saved from running into the disastrous cyclone last month by the warning it gave. The money thus saved in this one storm would pay the expenses of the Service for ten years.

The Microscope at Home.—In a lecture on the use of the microscope at home, by Henry Pocklington, the following directions are given for using the instrument to detect adulterated dry goods. Most people like to be sure that they get what they pay for. The microscope, in many cases, places the possibility of certainty on this point within the reach of its owner. Suppose, for example, that the lady of the house wishes to know whether the piece of silk she has set her heart upon for a dress is all silk, or a mixture with cotton, jute, or China-grass, and, if all silk, whether it has been loaded with dye and dressing. The microscope will set her mind at rest. Take a pattern of the silk, unravel the warp and weft, and examine it under the quarter-inch objective, and you will at any rate see whether all the little fibres of which the weft and warp are comprised look alike. That, of course, will not tell you whether the material is silk; but if you procure a piece of known silk, good raw silk, and study its appearance, and compare it with the suspected specimen, you will come to a sound conclusion very soon. Then take a little cotton and examine it to find that it consists of flattened tubes, curiously twisted, quite unlike the long cylindrical tubes of silk, and different again from the long consistent tubes of flax, with their attenuated ends and marked walls. Take wool and hairs of different kinds and examine them carefully, noting their peculiarities, and you will soon be able to tell whether your coat is all wool, or, as is much more probable, not; whether your wife's sable muff or seal jacket is what it professes to be, and will not improbably learn a lesson in the department of trade morality.

Solidified Petroleum.—Petroleum is solidified by Messrs. Frezon Dumont and Francoo, in which it only burns like tallow. They effect the solidification by mixing crude petroleum (after having undergone the first distillation) with 25% of the purified juice of plants belonging to the family of the *euphorbiaceæ*. The two ingredients are put in a boiler fitted with an agitator, and heated together to about 50°, agitating the whole till the mass becomes a uniform, milky fluid. When arrived at this state the mixture is distilled again and refined in the ordinary manner, when it solidifies and may be used equally well for lighting or as a lubricant.

Good Health.

Hot and Cold Drinks.

A correspondent of *Knowledge* calls attention to some of the disadvantages of hot drinks. Cold drinks, he says, are natural to man, though most people nowadays are so used to hot drinks that they do not feel satisfaction—really stimulation—unless they have them. Hot drinks are injurious to the tongue, for they deaden its sensation, and, after taking hot soup or drink, the tongue becomes quite numb and unable to taste the fine flavors of a dish. The teeth are greatly injured by them, and many dentists say caries (decay) is due to them alone. They crack the enamel, and thus allow caries to set in. When caries has once set in, hot drinks are a common cause of neuralgia.

Hot drinks are especially hurtful to the stomach. They cause irritation of the nerves of the stomach, and consequent mild inflammation of that organ, so that after a hot drink the stomach is red and congested. In time a debilitated condition is set up. A temperature of 100° Fahr. also destroys the active ferment of the gastric juice—pepsin—and so leads to indigestion. If the stomach is at all disordered, hot drinks give rise to much griping pain, and in many cases to vomiting. In cases of diarrhœa, too, hot drinks only increase it, while cold ones tend to lessen it.

Thirst is not common in winter, unless sugary, or hot spiced foods have been taken. In cold weather the air contains more moisture than in hot, and in cold weather there is less perspiration. Hot drinks increase the volume of heat in the body, and if that is not required it is quickly got rid of by the skin. Water is the best thirst quencher, but if simple food be taken, the need of drinks will be small. Many vegetarians drink nothing from month to month, the only fluid they get being the juices of the fruits which they eat. But pleasant drinks, like tea, coffee, etc., may be taken lukewarm for a time with little apparent damage. The least injurious is cocoa, made with plenty of milk, and allowed to stand until nearly cool. A good test is to apply the little finger to the drink, and if it be not too hot to it, then it may safely be taken.

Albumen in Cows' Milk.—Dr. Schmidt, Mulheim, has been investigating the nitrogenous bodies in cows' milk, about which so much diversity of opinion has hitherto prevailed. He says that three albuminoid substances are regularly present in the milk, viz.: caseine, albumen, and pepton. The average of seven analyses gave 2.43% of caseine, .38% of albumen, and .13% of peptone. Under certain circumstances the amount of albumen may increase until it equals that of the caseine. The pepton is formed from the caseine by a fermentative process; this ferment is destroyed by a boiling temperature, but its activity is not destroyed by salicylic or carbolic acid, so that in this respect it resembles the ferment that digests albuminoids. Since milk, on long standing, may lose 10% or more of its caseine by its conversion into peptone, it should be made use of as fresh as possible when employed for making cheese.

Remarkable Surgical Operation.—The Paris Academy of Medicine was recently informed by the operator that the young man on whom an operation was performed for the extraction of a spoon from his stomach has completely recovered from the effects of the hazardous operation, and is now enjoying his usual health. Interesting particulars are given of this operation, which was performed by Dr. Felizet. By the use of the Faucher tube, introduced through the mouth, the stomach was cleansed prior to the novel operation, which prevented the risk of peritonitis. An incision was then made in the epigastric region. In order to render the coat of the stomach easily accessible, M. Felizet employed the following contrivance: To the end projecting from the man's mouth he fitted a spherical vessel containing ether. This he heated by submersion in water of 60° temperature. The ether vapor rushing through the tube filled the stomach, which, becoming distended, was brought forward to the wound effected by the operator's knife. The spoon was thus readily found and extracted. It measured over nine inches. It had been accidentally swallowed by the man, a waiter at a *cafe*, in the attempt to imitate the feats of the famous sword swallower.—*Paris Cor. London Standard.*

A Growing Youth.—Jean Condoist has been brought to Paris as a medical curiosity from the Haute Caone. According to a medical contributor to a Parisian contemporary, this youth, aged 19, took a start on the 17th of May, 1881, being then six feet three inches high, and found one morning that he had grown an inch. Every week since then he has registered himself, and on the 14th of September this human beanstalk had gained nearly five inches; he grew five inches more before the 20th of January, 1882, and seven more before March 15th, and now stands 7 feet and 10 inches. All this has been accompanied by great pains in the back, and he stoops considerably; but since last June, it is his legs only that have grown, and his feet are already 24 inches long.—*London Pall Mall Gazette.*

How People Die.—Miss Nightingale has pointed out how constantly the mental state of the dying depends on their physical condition. As a rule, she tells us, in acute cases interest in their own danger is rarely felt. "Indifference, excepting with regard to bodily suffering, or to some duty, the dying man desires to perform, is the far more usual state. But patients who die of consumption vary frequently die in a state of seraphic joy and peace; the countenance almost expresses rapture. Patients who die of cholera, peritonitis, etc., on the contrary, often die in a state approaching despair. In dysentery, diarrhœa, or fever, the patient often dies in a state of indifference." Those who have carefully examined the dead on a battle-field, or in the streets after an *emeute*, are struck with the fact that while the expression on the faces of those who have died by gunshot wounds is one of agony and distress, the dead by sword have a calmer expression, though their wounds often seem more painful to the eye. A very careful observer, who was through the Indian mutiny, entirely confirms this. After giving several instances, he says: "A rapid death by steel is almost painless. Sabre edge or point divides the nerves so quickly as to give little pain. A bullet lacerates."—*London Spectator.*

A Poison for Tubercular Bacteria.—A paper was recently communicated to the Paris Academie des Sciences, by M. De Korab, on the action of helenine on the bacteria of tuberculosis. The facts mentioned deserve notice, although we fear that the hopes suggested are too bright to be realized. The bacilli was cultivated in bovine blood serum, which was daily heated for a week to effectually sterilize it, and was then coagulated by a temperature of 65° C. A guinea-pig having been rendered tubercular by inoculation and inhalation, small tubercular masses were taken from it, introduced into ten tubes containing the tubercular serum, and the tubes plugged after some helenine had been poured into three of the tubes. All were kept at a temperature of 37° C. for a week, and at the end of that time inoculation experiments showed that the organism in the tubes to which the helenine had been added no longer caused tuberculosis, which was readily produced by the contents of the other tubes.

An Incubator for Infants.—M. Tarnier, the Surgeon of the Maternity Hospital in Paris, struck by the great mortality among infants prematurely born, and those which are very sickly after birth, has conceived the ingenious idea of constructing a box which is almost exactly similar to the incubators used for poultry. This box is divided into two compartments—the lower one being used as a reservoir for hot water, while the infant is placed in the upper one, which is well stuffed at the sides and fitted with a sliding glass cover. The temperature is maintained at 86° Fahr., and M. Tarnier has found that by keeping infants in the incubator for a period varying from two days to six weeks, their vitality is enormously improved. He has made experiments upon five six-months children, six seven-months, and 13 eight-months children, and he has lost only two of them, whereas, according to his statement, three-fourths of them would have died but for this adventitious aid to vitality.

SAN FRANCISCO:

Saturday Morning, Nov. 18, 1882.

TABLE OF CONTENTS.

EDITORIALS.—New Treatment of Auriferous Ores, 321-32 Passing Events; Classes of Mineral-Producing Lands; Measurement of Auriferous Earth; Gravel; Bull's Process, 328 Discouraging Mining Operations; Jackson's Improved Ventilator; The Lincoln Pottery; Oate and Nozzle for Hurdy-Gurdy Wheels, 329. Patents and Inventions; Notices of Recent Patents, 332. The Denver Exposition—No. 13, 326.

ILLUSTRATIONS.—Apparatus for Reawin's Process of Treating Auriferous Ores, 321. Acme Ventilator, 329.

MECHANICAL PROGRESS.—Zinc in Boilers; American Inventions in the English Army; Adhesive Power of Nails and Screws; Transmission of Power by Wire Ropes; Care and Use of Belts; Steam Road Carriages; Pneumatic Tube for Philadelphia, 323.

SCIENTIFIC PROGRESS.—Explosives from Tar, Pitch, Coal Dust, etc.; is Fingal's Cave the Work of Man; Artificial Silk; Magnetic Observations; Crystallization of Silica from Fused Metals, 323.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 324.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Utah, 324-25.

USEFUL INFORMATION.—Are Toads Poisonous; Sewing Machines in Germany; Cement to Withstand Petroleum; Money Value of Science; The Microscope at Home; Solidified Petroleum, 327.

GOOD HEALTH.—Hot and Cold Drinks; Albumen in Cows' Milk; Remarkable Surgical Operation; A Growing Youth; How People Die; A Poison for Tubercular Bacteria; An Incubator for Infants, 327.

NEWS IN BRIEF, on page 332 and other pages.

MISCELLANEOUS.—Breathing in Bad Air Underground; Boys' and Girls' Aid Society; A Rich Montana Mine; Coal in Idaho; Shoes Without Leather; Treating Metals and Alloys; Mining Near Calistoga; Petroleum in Russian Locomotives; Practical Effect of Cold on Iron, 322. Working Copper Ores at Spenceville; Pure Hydrochloric Acid; Consumption of Coal in London, 326. The Secret of Success; Preparing Wood Type; Cotton Seed Oil, 327.

Roller Ore Feeder, Golden State & Miners' Iron Works

Passing Events.

Now that the somewhat exciting election times have passed, people are steadying themselves down to legitimate work again. In many places the snows have come and stopped work, and all prospecting in such localities has been given up. Many miners are coming into Salt Lake City from the Wood River and other mining regions of the northern country, where they will stay until the warm weather begins again.

News from the mines is just now rather meager as compared with what it usually is. We give in our "Summery," however, a very condensed abstract of what there is new.

It is worthy of note that not a week passes that we do not hear of more or less transfers of mining property. In fact, good mining property is always in demand now, but it must be meritorious and in some shape to pay soon. Undeveloped claims do not bring very good prices, nor are they much sought after.

DOWNEYVILLE BULLION.—A note from Luning, dated last Saturday, says that three tenmule teams arrived the day previous with 30,000 lbs. of bullion from the "silver caves" of Downeyville, and that on Saturday one 12-mule team, loaded with 25,000 lbs. of bullion, came in from the same place, making 55,000 in all. This bullion was all shipped on Saturday to the Melrose smelting works, Oakland, to be refined.

THE Tuscarora *Times Review* pertinently says: Where is there another camp, in or out of this State, that can show a production of $24,000 in 7 day's run from 10 stamps? That is the weekly output for the Navajo-Independence mill.

Classes of Mineral-Producing Lands.

It is important to prospectors and others locating mineral lands that they should understand the meaning of "rock in place" and "valuable mineral deposits," terms which are used in the U. S. Mineral Laws to designate the kinds of mineral land for which patent may be granted. By the use of these expressions it will be observed that the mineral-producing lands are divided into two classes—the one embraces lands where the mineral matter is within "rock in place," or geologically speaking, "in situ," and the second includes placers and all forms of deposit, excepting those in "rock in place." In this connection it is deemed a matter of importance to give the construction that the General Land Office places upon the expression, "vein or lode of quartz or other rock in place," to prevent mistakes in locating the two classes referred to, thereby saving to claimants considerable expense and delay.

The first section of the Act of Congress, approved May 10, 1872, reads as follows: "That all valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase," etc. The second section declares "that mining claims upon veins or lodes of quartz, or other rocks in place, bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits, heretofore located," etc. The sixth section refers to "a patent for any land claimed and located for valuable deposits."

It will be observed that in the first section of the Act the expression "valuable mineral deposits" is employed, while in the second and sixth sections the language is "valuable deposits." Allowing, however, that it was the intention of the law-makers, by this Act, to dispose of "valuable mineral deposits," the question becomes this: What is valuable mineral deposits? The meaning of the word valuable need not be discussed. Anything a person is willing to give money for, or that is useful or precious, or that has merchantable qualities, is valuable. The word deposit has always been construed by the Land Office to be a general term, embracing veins, lodes, ledges, placers, and all other forms in which valuable metals have ever been discovered.

As to "rock in place," in geology and among miners veins or lodes imply generally an aggregation of mineral matter found in the fissure of the rock which includes it, but are of great variety, veins differing very much in their formation and appearance. Lode (we use the language of the Commissioner) is a term in general use among the tin miners in Cornwall, and was introduced on the Pacific coast by emigrants from the Cornish mines, and signifies a fissure filled either by metallic or earthy matter. In several of the mining districts the terms lead and ledge are employed in the local regulations concerning mines. Lead is used to convey the same idea as lode, while ledge would seem to indicate a layer or stratum of mineral interposed between a course or ridge of rocks.

Veins may be either sedimentary, plutonic or segregated, or of infiltration or attrition, depending upon the peculiar formation or the mode of occurrence of the mineral deposits. There is also another form of deposit, different from either of those mentioned, called "contact deposits."

European miners mention still others, called in England "floors," in Germany "stockwerke," and a form of deposit known as "fahlbends." These latter are, more properly speaking, ore bearing belts, irregular in their dimensions, but presenting a certain degree of parallelism with each other. Similar in some respects to the fahlbends are the metalliferous zones or "amygdaloidal bends" which are said to exist on Mount Lincoln and Mount Bross, Colorado.

However, if the question were raised, neither of the forms of deposit known as contact deposit, fahlbends or segregated veins, could be accepted as true metalliferous veins, nor could it frequently be made to appear, without expensive excavation, whether the metal in the mine for which a patent is sought occurs in the form of a true vein or not.

But there is no reason for supposing that the terms were employed in their strict geological signification. The plain object of the law is to dispose of the mineral lands of the United States for money value, and whatever form of deposit can be embraced in the general phrase "vein or lode of quartz, or other rock in place," must under the law be sold at the rate of five dollars per acre.

It is evidently the policy of the Government to include as much land as possible under this designation, for the reason that as the most valuable metals and minerals occur in the several vein formations, it is desirable that the lands wherein they are discovered should be sold in limited quantities, thereby preventing the few from monopolizing large tracts, which ought to remain open to all for exploration and development, and for the further reason that the Government derives a larger revenue from the sale of the land of this description.

In fine, the Land Office includes in the first class all lands wherein the mineral matter is contained in veins or ledges, occupying the original habitation, location of the metal or mineral, whether in true or false veins, in zones, in pockets or in the several other forms in which minerals are found in the original rock, whether the gauge or matrix is disintegrated at the surface or not.

Measurement of Auriferous Earth.

There is nothing miners are more apt to make mistakes about than in calculating the amount and value of piles of rock and earth. And when it comes to figuring on the amount of quartz in place or the supposed yield of a bed of gravel, very few men are equal to it. When, in addition to calculating the amount, it is required also to tell the value of the pile of quartz or earth from average assays, there is another chance for possible error.

In the first place one wants to know the number of cubic feet of various kinds in a ton. In loose earth there are 24 cubic ft.; coarse sand, 18.6 feet; clay, 18 6; earth with gravel, 17.8; clay with gravel, 14 4; and common soil, 15 6. The volume of earth in embankment is less than in excavation, as the compression of earth in an embankment is in excess of the expansion of its volume in the natural state, the proportion being as follows: Sand, 1-7; clay, 1-9; gravel, 1 4. The volume of earth in bank exceeds that in excavation, in the proportion of three to two; when in large fragments it exceeds that in bank fully one-half.

In the drift mines of this State there is more attention paid to this question of measurement of gravel in place than anywhere else. Of course there is a great distinction made between gravel in place and gravel broken down to the condition of loose dirt. It is apparent that a cubic yard of dirt as it stands in its position in the mine, where it is so compressed as to require the drill of the miners and gunpowder for its extraction, cannot be contained in its loose or broken condition within the limits of a car or box the dimensions of one cubic yard. Careful observations and comparisons have demonstrated that in a majority of cases a cubic yard of standing ground will, when broken down, fill two cars of the capacity of one cubic yard each. The measurement of the ground worked in the famous Bald Mountain drift mine, in Sierra county, in this State, compared with the number of carloads extracted, confirm this statement. This gravel is very compact and hard, of course, and is in about as tight a mass as it is possible to put it.

In California the method of stating the yield of gravel varies in different localities. In some counties the standard is the car-load, generally 16 cubic ft. or a ton; but as there is no regulation size of car, and its dimensions and capacity depend on the size of the tunnel, this affords no standard of comparison. Again, the yield is sometimes expressed as so much to the superficial yard of channel ground; but here we meet with the difficulty that the hight of ground is not uniform, being in some places three feet, and at others four and five feet. In a report some years since of the U. S. Mining Commissioner, Mr. W. A. Skidmore, his deputy, in discussing this subject, said: "The only unvarying standard of comparison is the cubic yard; but unfortunately this is not in general use among the miners, and necessarily our means of comparison are limited. It is, however, well understood that gravel should pay from 50 cents to one dollar per carload of 16 cubic feet to be considered as profitable for drifting. We may therefore place the minimum yield at from 85 cents to one dollar per cubic yard of broken ground.

NEW PROCESS IN SULPHUR MINING.—Messrs. de la Tour du Brenil, having been engaged for ten years in the direction of sulphur mines in Sicily, were struck by the great loss involved in the ordinary process of separating the sulphur from its gangue. The idea occurred to them to increase the heat of the boiling water by the presence of a salt which it holds in solution. They fixed upon chloride of calcium on account of cheapness and the uniformity with which it maintains a temperature of 120° (248° F.). The bath contains 65% of chloride of calcium and can serve indefinitely. The apparatus consists of two rectangular vats which are coupled and inclined at an inclination of ten per cent. As soon as the operation is terminated in one of the vats the boiling liquid is drawn into the other, which has been previously filled with the ore. While the solution is going on there, which requires about two hours, the first vat is emptied and recharged; hence there is no interruption in the work and the bath is never cooled. A single fire is sufficient for the two vats, the heat being turned alternately from one to the other. This process presents the following advantages: 1. A cheap extraction of the sulphur, the cost being only about $1 per ton; 2. Great purity, analysis showing only one-twentieth of one per cent. of earthy residue and no trace of sulphurous or sulphuric acid; 3. Possibility of operating during the whole year, since there is no production of sulphurous acid, which is so injurious to the public health and to agriculture.—*Comptes Rendus.*

ALASKA MINES.—Advices from Victoria, B. C., say: Kenney May and others from Ominica came down on the *Otter* last evening. Two men who have discovered a new creek, and bring a sack of melon-seed gold, also came down. They are very reticent as to the locality and the value of the new diggings. D. E. Shay and Dutch Jake went out prospecting toward Nation river early in the spring and never returned. It is feared they were lost by falling through the ice.

Gravel.

People who read about gravel mines in California need not suppose the gravel is in the shape they see it in their garden walks or on beaches. The term refers to the water-worn pebbles or bowlders which occur generally as a more or less compact or conglomerate immediately overlying the bed-rock. There is considerable heterogeneity in the lithological character of the conglomerate, though pebbles or bowlders of a quartzose character generally greatly preponderate. Usually, subordinate to the quartzose pebbles or bowlders, are others which are sometimes foreign to the lithology of the district, and have been transported long distances. The cementing or binding material is sometimes calcareous, but generally ferruginous and siliceous.

The term red gravel is given to the brownish or reddish colored conglomerate which forms the top and overlies the blue gravel, which is the bluish, greyish or greenish colored gravel nearest the bed rock.

The gravels owe their color to the difference in degree of oxidation and hydration of the iron constituents which form the cementing or binding matter of the conglomerate. The "blue gravel" has very often iron in the form of finely-divided iron pyrites, and to the presence of this mineral and of some of the ferrous salts most probably is due the peculiar color. The oxidation of the ferrous salts and the pyrites converts the iron into anhydrous sesquioxide, which imparts the red color to the gravel. The addition of water changes the anhydrous to the hydrous sesquioxide, and the gravel assumes a hue more or less brown, depending upon the degree of hydration, and is seen as a variety of red gravel.

The color of the gravel is entirely independent of the source from which it has been derived. That the blue gravel is rich gravel cannot be true other than in a relative sense. It is true that the blue gravel is always richer than the red gravel; but *per se*, the color of the gravel is no criterion of its absolute value. The gravel is richer nearer the bedrock than in the upper portions of the deposits, because of the greater specific gravity, etc., and the color of the gravel in the lower portions is blue, because the lower horizons are less exposed to the oxidizing influence than the upper horizon of the deposit, where the atmospheric agencies have had access, and have changed the original blue color of the deposit to the red color now characteristic of top gravel. The gold occurs disseminated throughout the greater portions of the red and blue gravel. It is not uniformly distributed, but is finer as regards its texture, and less abundant in the top gravel than below in the blue gravel. The pay gravel is generally confined to the blue gravel, and in some mines, especially where a more expensive process of drifting is adopted, the pay gravel rarely extends more than three to five feet above the bedrock. Where a schistose rock forms the bedrock, the gold is often found included between the laminæ several inches below the bedrock.

Bull's Process.

At the Liverpool Polytechnic Society meeting on Monday, Mr. John Siddley, the President, in the chair, Mr. Vaughen W. Jones read a paper on Bull's process for the manufacture of iron and steel direct from the ore, of which Bull's Iron and Steel Company, Hackins-hay, are the sole proprietors. The writer described the operations of making pig-iron in the ordinary blast furnace. The crude iron produced in the ordinary blast furnace contains, in addition to carbon, all the phosphorous and a large portion of the sulphur which has been placed in the furnace, either in the ore, fuel or flux, together with some silicon. These substances are reduced from the phosphoric acid, sulphuric acid and silica in the ore by solid carbon present in the lower portion of the furnace. In the upper portion of the furnace the iron is reduced to a metallic state without reducing these substances, the carbonic oxide not having sufficient affinity for oxygen to absorb the same from either sulphuric acid, phosphoric acid, silica or oxide of manganese. In Bull's process no solid carbon is used in the furnace, which is charged with nothing but iron ore and flux—usually limestone. The furnace is worked exclusively with gas, which is delivered into it in a very highly heated state, direct from the producers. Highly heated air is also introduced in sufficient quantities to burn about 10% of the gas, and maintain the furnace at the high temperature necessary to allow the withdrawal of the iron or steel and cinder in a fluid state. Under this system the gases rising through the ore and flux are carbonic oxide and hydrogen in equal volumes, together with the nitrogen derived from air which has been blown into the furnace. These gases being produced entirely outside the furnace, there is no zone of gasification, but only the zone of fusion, reduction and carburisation. The zone of preparation is removed from the furnace by an apparatus. By the aid of diagrams and drawings, Mr. Jones gave an exact description of the process, the advantages of which are that iron or steel ingots can be produced in any district, at a cost much lower than the most inferior pig-iron under the present systems, owing to the enormous increase of the output of the special furnace designed by the patentee.

Discouraging Mining Operations.

How strange it seems that a large proportion of the population of this State should see fit to ridicule mining operations. Not only to ridicule and decry them, but to pursue the same course toward those individuals who carry on mining as a business. Because the shallow placers of California have been despoiled of their millions, and are no longer worked, this class of people argue that mining is a thing of the past. We find that the moment a mining enterprise is mentioned in the presence of many, they ridicule it at once, setting down the originator as visionary in his undertakings, or as a dishonest speculator in "wild cat" stocks. Local intermixers and half-fed Bohemians seize with avidity upon any trifling occurrence upon which they can base a sensation article "ventilating the stupendous swindling transactions of mining operations." In most of these articles, directors, secretaries and superintendents are handled without gloves, and represented as gnawing fat on assessments stolen from the pockets of gullible shareholders. All varieties of gross ridicule and caricature are indulged in, and, generally, the reader is left to infer that *all* mining incorporations are South Sea bubbles—grand swindling schemes—and that most mines exist only in the imagination of the shareholders; and, furthermore, that all assessments are divided pro rata or otherwise among the sharp "insiders." These fallacious doctrines, so generally inculcated, all have their effect on readers whose minds are not well balanced, and often prove a powerful lever in overthrowing the most beneficial of industrial enterprises.

We certainly have a right to expect that newspaper publishers, at least, should recognize the fact, that we owe our very existence, as Californians, mainly to our mines, and to discourage mining undertakings indiscriminately is seriously sapping our vitality. If it is their aim to encourage our people in their legitimate vocation, they should rigidly adhere to a course tending to the rapid development, rather than the retarding of our mining interests.

It takes money to develop mines, as it does to start almost any other business; but some of these people think a mine should pay as soon as a pick is struck in it, which would be like a building paying rent when the foundation is laid. A building must be finished before it yields an income, just as a mine must be open before it will pay; but the difference is in favor of the mine, for something may be derived from it, however little, from the start.

Our great misfortune is, that we have in our zeal undertaken to develop more mines than we have capital to go on with. We want more capital to develop new mines, as the old ones will take care of themselves. To read some of our papers, Eastern and European capitalists, whose aid we require, might infer that by far the greater majority of our mines are "wild cat" speculations, and the trustees, superintendents and presidents of the companies a set of unscrupulous, grasping thieves, whose only business is to swindle stockholders. Those charges are only made indiscriminately and in general terms, the penny-a-liners being afraid or being unable to mention names; but the effects these foolish articles have on those who gain their information on these subjects from the newspapers is highly injurious to the State and the whole Pacific Coast. Justice should be used at least to deserving enterprise; and, when dishonest transactions are brought to light, no class of the community will be more eager in bringing the guilty parties before the law than the people interested in mining operations.

LEAD PRODUCTIONS OF THE WORLD.—In his report upon the Linaree mining district, Vice-Consul Sopwith states that the world's production of lead is thus distributed: Great Britain, 50,000 tons; Spain, 120,000 tons; Germany, 90,000 tons; other European countries, 50,000 tons; America, 100 000 tons, and other countries 3,500 tons=413,500 tons. Spain thus holds the first place in the list of producers. Of her total production of 120,000 tons 67,000 tons are derived from the Linares district, in which no less than 805 mines are registered. Of this number, however, comparatively few are actually worked on a large scale, there being only 53 in which steam power is used. The total number of steam engines employed is 130, and the fact that 57 of these belong to English companies will give some idea of the extent to which the lead mining industry is carried on by British capital. Even in the Spanish mines, too, English foremen and engineers are largely employed, and most of the machinery and pumping engines in use are of English make.

THE railroads carried a million persons into Philadelphia during the week of the Penn celebration, but trade was almost at a standstill, neither visitors nor residents buying much while the show was going on. The hotels and theaters made money out of the crowds, but the merchants lost heavily.

THE running of a railroad train on Sunday is not a violation against the law of doing business on the Sabbath day in the opinion of the Court of Appeals in the Commonwealth of Kentucky vs. the Louisville & Nashville Railroad Co. The Court said that the running of the train was a work of necessity.

DURING the past week 854 immigrants arrived in California by overland railroad.

Jackson's Improved Ventilator.

We illustrate on this page an improved ventilator for soil pipes, chimneys, flues, etc., or for any place in which impure air or foul gases are liable to generate, or wherein there is imperfect ventilation. Mr. P. H. Jackson's invention, which was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, consists in the provision of means for inducing an independent draft or current in such relation with the body of impure or foul air or gas that a part shall surround and another part be inclosed by said body of impure air or gas, whereby it may be acted upon to better advantage. The means which have been adopted to this end consist in a main hollow conical casing or shell, in which is supported a second and smaller conical shell or casing, whereby an air space is formed between it and the main casing. In this second casing is another hollow conical casing, the base of which has about the same diameter, and is formed to the base of the second casing. Its frustrum is smaller and extends to the rear end of the second casing, but is not joined thereto, thus forming a space between it and the said casing, said space opening out to the rear. The device is swiveled upon the top of the soil pipe or flue, the foul or heavy air or gas from which is drawn through a proper induction pipe or channel into the space between the second conical casing and the interior one. A current of pure air passes through the outer and innermost casings, and at the rear end the outer current surrounds and the inner is enclosed by the body of foul air, which their passage has induced from the soil pipe or flue to escape through the space between the second casing and the inner casing. To provide for an increased draft,

casings are provided, through which the pure air passes, with screw flanges on their inner surface.

In pipes where foul air or gas has accumulated, or in which there is imperfect draft, the air being heavy, will not pass off. In all ventilators of this class an independent draft is effected, in such relation with the body of foul or heavy air as to cause the latter by induction to rise and clear the pipe. In some devices the body of foul air is surrounded by, and in others it surrounds the actuating draft or current, in either case but imperfectly inducing the latter, as it acts upon one edge only. But in this construction Mr. Jackson has combined both features—surrounding and being inclosed by the air to be induced—whereby the whole body of the latter is acted upon and drawn out.

With this explanation of the principles of Mr. Jackson's device, its operation will be readily seen when the engraving is examined. The hollow conical casing or shell, the frustrum terminating on a pipe, is shown at *b*. The second or inner casing is shown by *a*, and *c* represents the space between the two casings, this space being connected with the soil pipe *d*, as shown. The arrows indicate the direction of the air currents.

A QUESTIONABLE FOSSIL.—At a recent meeting of the New York Microscopical Society, Oct. 10th, Dr. William B. Carpenter, of London, summarized his investigations of the structure of Eozoon Canadense, and exhibited many specimens under the microscope. Dr. Carpenter holds to the theory of the organic origin of this much disputed fossil,

The Lincoln Pottery.

In a recent issue we made mention of an important mining enterprise in western Placer, commonly known as the Lincoln coal mine, but among the various and important industries, under the head of mining, for which Placer county is justly celebrated, none holds a higher place among substantial and permanent industries than does the manufactory known as the Lincoln Pottery, situated at Lincoln, Placer county, and in the immediate neighborhood of the coal mine. Adjacent to the coal fields, of which we have heretofore spoken, is situated an odd elevation of land, known as Rocky Ridge, which rises abruptly at its eastern extremity, from a comparatively level country, to the height of about 100 ft above the level of the plains. Its eastern end is about eight miles west of the base of the foot-hills of the Sierra Nevada mountains, and the ridge extends westerly about two miles, gradually sloping to a level with the Sacramento valley.

From the eastern and abruptly sloping end of this ridge is taken the clay from which the Lincoln pottery derives its manufacturing material. Here, perhaps, is one of the largest deposits of fine clay in the world. It is obtained at comparatively no expense by simply digging down the end of the hill and hauling it to the works, about half a mile distant, on the California and Oregon railroad. Ages will not exhaust this deposit, which is from 20 to 30 feet in depth.

Messrs. Gladding, McBean & Co., who own the pottery, keep constantly employed a large force of men, which, together with the force at the coal mines, makes Lincoln a lively and flourishing town. Here are manufactured beautiful vases, urns, flower pots, and vessels of various design. The principal manufactures, however, are ironstone sewer pipe, chimney tops, fire brick and terra cotta ware. In burning these articles, large amounts of wood are consumed, which also adds much to the welfare of this vicinity.

At the late Mechanics' Fair, among many interesting and beautiful articles exhibited as the productions of this pottery, was a magnificent large double antique nuptial vase, which is a reproduction of one exhibited in Metropolitan Museum, Central Park, New York, and which is known to be 2,200 years old. It was made to commemorate a princely marriage, and after the death of its owners was placed in their tomb, where it remained for more than 20 centuries, until taken therefrom and sold to its present owners, the Misses Brace, who loaned it to the above museum, where it was much admired for the unique composition of the vases, and as showing the degree of perfection attained in the ceramic art at that early period. As the original of this vase had never been copied, owing to the difficulty of making, joining, drying and burning so large a piece, and the lack of competent artists, Messrs. Gladding, McBean & Co., who have one of the most skillful workers in plastic clay in the United States, caused this reproduction to be made in order to show their artist's skill and give to the people of this coast an opportunity to see an unique and beautiful piece of terra cotta. Placer county should be credited with four big marks in mining enterprise gold, iron, coal, and last, but not little, terra cotta.

DISASTROUS floods are feared in and around Paris, France, as the rivers Seine and Marne are rising rapidly.

Gate and Nozzle for Hurdy-Gurdy Wheels.

A new nozzle and an adjustable regulating gate for the admission and direction of water to water wheels has been invented by Samuel N. Knight, of Sutter Creek, who has just received his patent through the MINING AND SCIENTIFIC PRESS Patent Agency. The invention is intended to be applied to that class of wheels which are driven by the momentum of a stream of water, which is delivered against the buckets from a nozzle under a high pressure, these wheels being known as hurdy-gurdy wheels. By this invention the supply of water can be regulated to the power required with great minuteness, and the gate may be readily opened or closed, whatever may be the pressure.

The nozzle is a narrow, but of considerable depth, and the discharge end is curved to the shape of the wheel, its concavity closely following the rim of the wheel or buckets. The nozzle is divided longitudinally by partitions, which extend from the gate chamber to the front, so that when the nozzle is full of water the latter will be divided into three or more separate streams. The gate has a height equal to the entire depth of the nozzle, and fits closely enough in its diameter to cut off the supply of water from the nozzle when closed. This gate moves transversely across the pipe or nozzle, and is something more than four times the width of the nozzle opening. At one side of the gate is formed a slot, which is the full size of the nozzle, so that when it stands opposite the nozzle all three of the passages between the partitions are exposed to receive a full head of water from the conveying pipe. By the side of this opening is another opening, which extends two-thirds of the depth of the nozzle, and when brought opposite to the nozzle will admit water to the two lower compartments, only leaving the upper one closed. One opening in the gate is of a height equal to the lower compartment only, and when it is brought opposite the nozzle only this compartment will be supplied with water.

More or less compartments may be made through the nozzle if it is desired to graduate the amount of water discharged on the wheel, and therefore the amount of power more closely.

In order to move the valve more easily, under the great pressure to which it is subjected, the inventor employs a pressure cylinder, having a piston within it. This cylinder is set horizontally, and is on the line of motion of the gate, and the piston-rod is fixed to the gate and to the piston, so that the movement of the latter will open or close the gate, more or less, as desired. A suitable lever is connected with the valve-stem, and by moving the valve in either direction, water is admitted into the cylinder, and by its pressure upon the piston, opens or closes the gate. A suitable indicator shows the position of the gate.

THE recent reports of the discovery and development of gold and silver mines at various points in Central America continue to excite attention. A late issue of the Panama *Star and Herald* gives particulars of progress made in gold mining in Antioquia and Tolima. Some valuable mines owned by the Colombian Government are to be sold in December, and other mines are being worked successfully by companies formed in this country and in Europe. Recently a number of companies have been formed for the purpose of prospecting, and indications grow that a swarm of gold-hunters will soon be roving over the rocky backbone of the mountains that run along the narrow strip of territory uniting North and South America. These countries have long lain stagnant under the sway of the mixed people that sprung up after the Spanish conquests, but now money, machinery and enterprise will pour in upon them as long as mining enterprises prove remunerative.

EXTRAORDINARY BLAST.—There are at present some very interesting experiments being carried out at Messrs. J. W. Pease & Co.'s limestone quarries, Weardale. The output at the present time is estimated at 200 tons per week. The ordinary system of hand drilling has been adopted from the commencement until very recently, when a number of deep holes have been drilled by machine power. One of the holes, described and known by the quarrymen as the Jumbo hole, has been drilled to a depth of 18 ft., by 2 in. diameter. The hole was drilled and completed in about four hours, and by an excellent system in charging the hole, was blasted, using 450 lbs. of powder, whereby it is estimated that over 3,000 tons of rock has been removed, and is acknowledged to be one of the largest and most effective blasts ever known in the district, and at the same time the output can be very considerably increased. The machine employed at these extensive quarries is the well-known Cranston patent rock drill, of Newcastle-on-Tyne.—*London Mining Journal.*

THE coal mines of Dakota will soon be an important feature. Seven foot veins have been opened. It is only of medium quality, being formed under slight pressure and not having a solid rock roof. But judging from all coal countries we may infer that under this vein there will be others at a greater depth and of much better quality. This coal retails at from $3.50 to $4 50 per ton.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. **New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.**

PACIFIC IRON WORKS

1850. 1882.

RANKIN, BRAYTON & CO.,

127 First St., San Francisco, Cal.

BUILDERS OF

MINING MACHINERY.

Plants for Gold and Silver Mills, embracing the latest and most improved machinery and processes for base and free ores. Water Jacket Smelting Furnaces for silver, lead and copper ores, with new and important improvements, superior to any other make. Hoisting Works, Pumping Machinery, Chloridizing Furnaces, etc. We offer our customers the best results of thirty years' experience in this special line of work, and are prepared to furnish the most approved character of Mining and Reduction Machinery, superior in design and construction to that of any other make, at the lowest possible prices. We also contract to deliver, in complete running order, Mills, Furnaces, Hoisting Works, etc., in any of the Mining States and Territories. Estimates given on application. Send for illustrated circular.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequaled by any other published embracing the subjects treated. Post-paid, $7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. A valuable and carefully written work. Postpaid, $3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by Dewey & Co., S. F.

PHILLIP'S EXPLORERS' AND ASSAYERS' COMPANION (Third Edition). Price of Vol. 1, post-paid, $6. Sold by Dewey & Co., S. F.

COPP'S AMERICAN MINING CODE, to replace Copp's Handbook of Mining Laws, now out of print. United States, State and Territorial Mining Laws and Land Office Regulations; Digest of Land Office and Court Decisions; List of Patents Issued, and Dr. Raymond's Glossary, with Forms for Mechanics' Liens, Location Notices, etc. Price, postpaid, in paper, 50 cts. Sold by Dewey & Co., S. F.

THE EXPLORERS' MINERS' AND METALLURGISTS' COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 Pages and 83 Engravings. Price, bound in cloth, $10.50. Sold by Dewey & Co., S. F.

CHURCH'S "COMSTOCK, LODE, ITS FORMATION AND HISTORY."—Illustrated with diagrams and colored charts showing sections, ore bodies, etc. Post-paid, $7.50. Sold by Dewey & Co., S. F.

U. S. MINING LAWS AND COAL LAND LAWS.—Containing instructions and blank forms. Postpaid, 50 cents. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

Carson and Colorado Railroad.

(NARROW-GAUGE.)

The Company announce the completion of its line March 1, 1882, to CANDELARIA, Columbus Mining District, Esmeralda Co., Nev., 158 miles from Mound House (Junction with Virginia and Truckee Railroad).

STAGE CONNECTIONS,

At Hawthorne with U. S. Stage Company's daily coaches for Aurora (26 m.); Bodie (37 m.); Lundy and Bridgeport.

At Luning (125 miles from Mound House) with Gilmer, Salisbury & Co.'s tri-weekly stages (leaving Tuesday, Thursday and Saturday mornings) for Grantsville, Belmont and Tybo.

At Belleville (150 miles from Mound House) with Belleville and Independence Stage Co.'s stages for Benton (40 m.), Bishop Creek, Big Pine and Independence.

At Candelaria, with U. S. Stage Co.'s stages for Columbus (8 m.), Silver Peak, Montezuma, Alida Valley, Gold Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento Reno, Carson and Virginia R. R. Ticket offices.

This is the direct and natural route for Passengers and Freight, to points in Southern Nevada, Mono and Inyo counties, California. The line, laid with steel rails and red wood ties and equipped with new and first-class rolling stock, is penetrating new and most promising Mining Districts which are now attracting deserved attention throughout the country.

For information on through freight rates apply to

H. M. YERINGTON, Gen'l Supt. D. A. BENDER, Gen'l Freight & Pass. Agent, Carson, Nev.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

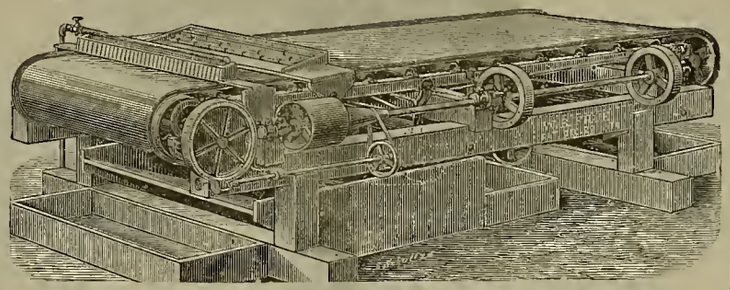
PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hockley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description. Steel Shoes and Dies that last three times as long as any iron.

WAREROOMS: 92 & 94 Liberty St., New York,

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of **Morey & Sperry** are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of **Morey & Sperry,** will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-Class.

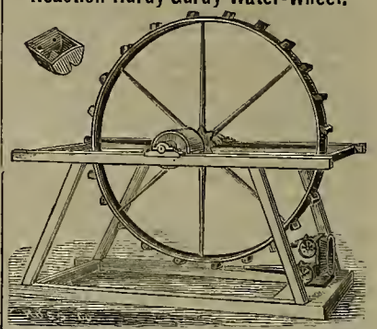
MOREY & SPERRY MINING MACHINE CO.

Engraving. Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

PELTON'S PATENT

Reaction Hurdy Gurdy Water-Wheel.



This Wheel will be guaranteed to purchasers to give 83% of the theoretical power of water. ☞Send for circular to L. A. PELTON, Nevada City, Nevada Co., Cal.

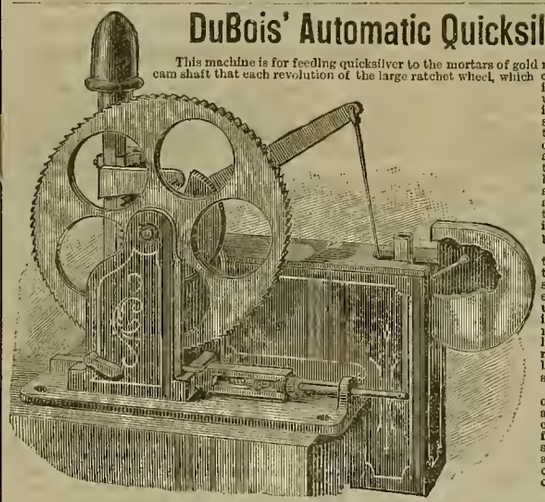
DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.

The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.

A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.

Price, complete, $75.

For Sale by } **WHITNEY & MARSHALL,** { Sole Agents

22 & 24 Fremont St., San Francisco.

Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

New Treatment of Auriferous Ores.

(CONTINUED FROM PAGE 321.)

when unscrewed of the mercury or amalgam being run off from the said oups, through which a corresponding hole is bored and tapped to permit of easy removal by a ring bolt. A wire or bar, *k*, which may be composed of wires stranded together, is passed through the eyes of the screws, *i i*, and secured thereto hy lock and key, so as to prevent the unauthorized withdrawal of the contents of any of the pans; *l* is a trough carried above the pans, and having a screw-bladed shaft, *m*, which revolves therein by means of the wheels, *n n*, driven from the shaft, o, which screw feeds the crushed ore fed from the hopper, *p*, to each of the pans hy means of shoots or spouts, *q*. The regulating tube, *p'*, is capable of being shifted np or down so as to regulate the supply of crnshed ore to the trough, *l*, *r r* are sliding shutters (shown in section at Fig. 3) fitted to the bottom of the trough, which doors regulate the openings, *r*, so as to allow the requisite quantity of ore to pass through in a given time; *s* is an overflow pipe, which carries off the superfluous ore as it collects at the further end of the trough, from whence it is returned to the feeding hopper, *p*; *t t* are overflow pipes to permit the surplus water, together with the baser metals and gangue in a finely divided condition, to escape from the pans by the troughs, *t' t'*, to receivers, *u*. Two or more outlets may be applied to each pan when required at different levels; *v v* are pipes running the length of the pans, provided with cocks; *v' v'*, for supplying water to the said pans.

In operating the machine, the cups, *h*, are filled with mercury (for treating ores containing ingredients injurious to ordinary mercury he uses specially prepared mercury), water is then run into the pans through the cocks, *v'* up to the level of the outlet, *t*. The pestles are then set in motion hy throwing the bevel wheels, *d*, into gear, forcing the pestles to revolve in the pans hy means of the arms, *c'*. The hopper, *p*, being filled with ore crushed to the required size, the ore falls into the trough, *l*, at such a rate as may be allowed by the adjustment of the shutters of the shoot, *p'*. The screw, *m*, being set in motion, carries the ore along the trough, and causes it to pass in a uniform layer over the adjustable apertures, *r'*, the screw being so connected with the shaft that it shall revolve at a proportionate rate with the pestles supplying the necessary quantity of ore per minute to each of the pans. The ore, it will be observed, will be thus supplied gradually and in the proper quantities to the pans, and by the crushing and grinding action of the pestles on the pans it will be reduced to a finely divided condition, in which state it is presented to the mercury in the cups, *h*. The mercury catches the amalgamable portion of the precious metal contained in the pulverized ore and thus forms the required amalgam. During the process the water, together with the baser metals and gangue, is continually flowing through the overflow pipes, *t*. When it is required to withdraw the mercury or amalgam the wire rope or rod, *k* is withdrawn from the eyes of the tap screw, and the mercury and amalgam run off as required.

The extent to which an invention for treating ores such as Mr. Readwin proposes to deal with can he applied can scarcely be estimated, as the difficulty would be to find those who having poor or refractory gold ores to treat would not avail themselves of it. Mr. Readwin has already been very successful in his Welsh experience, and seems likely to have a good opportunity of testing the invention in India, but it is probable that the greatest results will he obtained in Ireland, as it is confidently believed that it will now be practicable to open up the Wicklow gold field, which is acknowledged to contain great wealth, and to be capable of yielding large profits when thoroughly developed.

News in Brief.

THE Duke of Newcastle is to visit Florida and California.

THE expenditures on the Brooklyn bridge to date amount to $14,045,684.

THREE shocks of earthquake were experienced at Mendocino Saturday.

A TEN-YEAR-OLD boy was shot by a playmate at Prescott, A. T., Saturday.

NINETY sailing vessels and eight steamers were lost on the Atlantic coast during November.

THE free canal amendment to the New York Constitution was adopted Tuesday by over 200,000 majority.

THE steamship *Angelica*, plying between Gelfe and Hull, has foundered in the North sea. Forty persons were drowned.

THE latest advices from Chile state that peace negotiations have been renewed with Peru, it is reported, on the basis of the cession of Tacna and Arica.

THE *Ting Yeung*, the formidable ironclad that has just been built in Germany for the Chinese Government, is to he lighted by 240 Edison electric lamps.

BARON NORDENSKJOLD is getting ready for another Arctic expedition, which is to set out from Stockholm next summer under the patronage of Wilhelm Schenlenck, a Berlin merchant.

THE proposal of Germany to prohibit the importation of American pork, etc., meets with general opposition, as Russian and Austrian imports remain unmolested, and the German trade will suffer.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING NOVEMBER 7, 1882.

267,055.—CLAMP FOR ADJUSTING DOOR-KNOB ROSES—C. V. Slackman, Oakland, Cal.

267,056.—PAPER FILE—H. H. Blake, Chico, Cal.

267,160.—ROTARY ENGINE—John H. Darragh, S. F.

267,103.—TUCK FOLDER FOR SEWING MACHINES—Charles M. Dexter, Sacramento.

267,249.—WHEEL TIRE—Plummer & Turpin, Olympia, Wash. Ter.

267,117.—CAR COUPLING—T. A. Smith, Arbuckle, Cal.

267,121.—SAW TOOTH—A. J. Van Drake, S. F.

267,250.—BULKY HAY RAKE—W. P. Prall, Colusa, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CLAMP FOR ADJUSTING DOOR-KNOB ROSES.—G. V. Blackman, Oakland Cal. No. 267,055. Dated Nov. 7, 1882. This invention relates to a new and useful device for adjusting and securing the roses of door knobs, and has special relation to those roses which are provided with pins, and are secured by forcing these pins into the door. The invention consists in the employment of a spindle or shaft having firmly fixed upon one end a block having a sliding ring, serving as a gange, and a recessed inner face in which one rose is adapted to fit, said spindle having upon its outer end a loose block with a face similar to the first for receiving the opposite rose, this loose block being moved inwardly upon the spindle by means of a nut screwed upon the end of the spindle. A sliding ring or band upon the stationary block determines the correct adjustment of the two roses. Knob roses have been heretofore ordinarily screwed to the door; but there are such objections to this manner that roses have lately been extensively made, the inner faces of which are provided with pins cast upon them and adapted to penetrate the door to secure the rose. These roses are usually put on by driving them, a plan which is liable to bruise or mar the metal. The object of this invention is to provide a means for forcing the roses against the door, so that their pins will secure them, and at the same time to adjust them precisely with relation to each other.

LIFTING-JACK.—O. H. Hoag and N. B. Hervey, Santa Rosa, Cal. No. 267,081. Dated Nov. 7, 1882. This invention consists in certain improvements in lifting jacks, and it consists of a standard fixed to a base sliding axle support moving in guides upon this standard, the two having their edges notched or serrated to receive the hinged links, one of which is fixed to the lower end of a lever, and with it serves to raise the sliding support, while the other is fixed to the standard, and, engaging the notches or serrations upon the sliding support, retains it at any desired hight, or it is used in conjunction with the other link and the lever to let it down.

PAPER FILE.—Henry H. Blake, Chico, Cal. No. 276,056. Dated Nov. 7, 1882. This is a new and useful paper file, and it consists in a stationary pad or stick provided with a groove, and securing-pins adapted to be sustained from a wall by means of a hed plate, in combination with a swinging pad or stick provided with a tongue and holes to receive said pins, and hinged to the edge of the stationary pad, with which it is held in relation by means of springs. The object of the invention is to provide a simple and effective means for holding a file of papers, or for securing posters, play-bills, etc., which are usually tacked or pasted upon the walls.

FEEDER FOR THRASHING MACHINES—John Ducker, Santa Rosa, Cal. No. 267,066 Dated Nov. 7, 1882. This ie a device for feeding unthrashed straw to the cylinder of a thrashing machine, and regulating the same. The essential part of the invention liee in the adjustment of the frame of the arm-supporting shaft forward and back and up and down, and in a corresponding adjustment of the connecting rods, so that wet, green or dry straw may be fed with equal facility.

CAR-COUPLING.—Theron A. Smith, Arbuckle, Colusa county, Cal. No. 267,117. Dated Nov. 7, 1882. This improvement in car-coupling consists mainly in an attachment which may be secured to any ordinary drawhead, and which is provided with a device for holding the pin up until it is released by the approaching link, when it will drop through the latter.

Recent Contributions to the California State Mining Bureau.

PLANT FIGS.—Let us urge the planting of figs in variety and plentifully in all homesteads in California where the fig will mature. Children seven years old can plant cuttings of fig trees that will bless them and the older members of their families bountifully when 10 and 12 years of age. It pains us to ride over one of God's most fruitful countries in the dry and thirsty season and find only one place in many where people have blessed themselves with tree of any kind. Thousands are shadeless and without fruit in our great valleys who can in three to five years have plenty of bearing fig trees by sticking a few cuttings in the ground this fall and taking a little pains only with these sources of healthy food. Plant fig trees!

A BILL has been introduced in the Vermont Legislature taxing railroads. It provides that the Governor shall appoint three appraisers to appraise all the railroad property in the State, at its actual cash value, and an amount of the same in proportion to the miles of track in each town shall be set in the list of said town for taxation.

THE Commissioners of the Garfield Monument Fund have chosen Governor Cornell as President; ex-Brigadier General James and Cyrus W. Field, Vice Presidents; Colonel D. E. Austin, Secretary; Colonel Emmone Clark, Treasurer. General Hancock, William H. Vanderhilt and Colonel E. T. Shepherd are appointed Commissioners, and General James W. R. Stewart and Edward L. Thorne a committee to solicit works of art and to arrange for their transportation for the Washington Exhibition.

Pacific Coast Weather for the Week.

[Furnished for publication in the PRESS by NELSON GOROM, Sergt. Signal Service Corps, U. S. A.]

The following is a summary of the rainfall for each day of the week ending 11:58 A.M. Wednesday, Nov. 15th, for the stations named:

Date.	Thursday.	Friday.	Saturday.	Sunday.	Monday.	Tuesday.	Wednesday.	Totals.
Olympia.	.00	.00	.00	.00	.00	.80	.01	.87

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,

No. 252 Market St., S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging Agents. We intend to send none but worthy men.

G. W. MCCREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.
L. L. WOODMANSEE—Nevada State.
B. W. CROWELL—Los Angeles county.
L. WALKER—Butte, Tehama and Shasta counties.
E. A. WILLIAMS—San Francisco.
S. E. BARER—Eastern States.
J. WILTSE, Amador county.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter*.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 502 Taylor st. Price, $4.

To Engineers and Draftsmen.

WANTED.—A good wood engraver. Also, a draftsman, who can make pen and ink drawing on paper or stone. Apply at this office.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

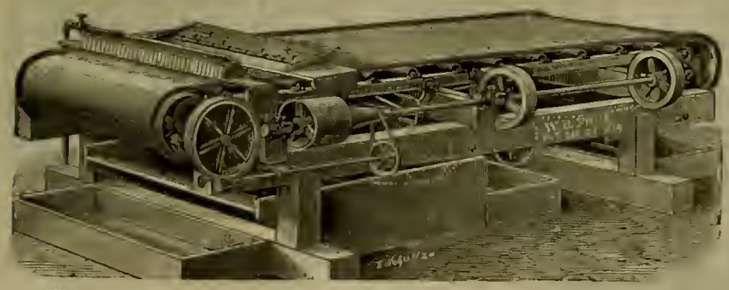
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that *all shaking motion* applied to an *endless traveling* belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make *users* of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of $1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street, - - - - SAN FRANCISCO, CAL.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

☞ The Giant Powder Company have also purchased from Mr. Nobel, the Inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 216 Front St., S. F.

THE CONSUMERS' COMPANY.

VULCAN B B,

The Best Low Grade Explosive in the market. Superior to Black or Judson Powder

VULCAN NOS. 1, 2 AND 3,

The best Nitro-Glycerine Powders manufactured. Having secured large lots of the best imported Glycerine at low prices, we are prepared to offer the mining public the very strongest, most uniform and best Nitro-Glycerine Powder at the very Lowest Rates.

SPECIAL INDUCEMENTS IN PRICES.

Vulcan B B Powder (in Kegs or Cases) is Unequaled
For Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

The Central and Southern Pacific Railroads Use Vulcan Powder and no Other.

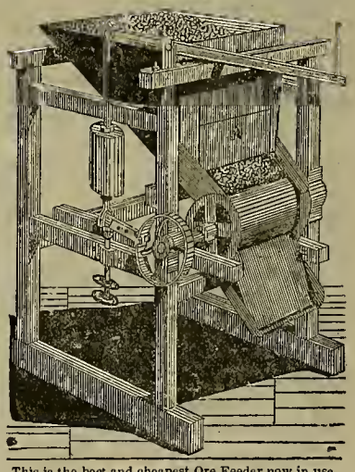
THE ROLLER ORE FEEDER.

Patented May 23, 1882.



This is the best and cheapest Ore Feeder now in use.

It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupellation Furnaces, Market Kettles, Wire Rope Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

Through Dewey & Co.'s Scientific Press Patent Agency.
No. 252 Market Street. Elevator, 12 Front St., S. F.
Telephone No 658.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long established, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

FOR SALE.

THE PUTNAM HOTEL AND lot, in the town of Auburn, Placer county. The house is a large three-story building, new, and contains 60 rooms. It is in first-class condition, with all modern improvements, and is doing a fine business. It is furnished throughout with the best furniture. Persons who contemplate engaging in the hotel business will find this a rare opportunity, as the property is good and in a thriving town. Bids for the property will be received in writing by the executor of the estate, ADDISON PUTNAM, or by J. T. KINKADE, his attorney, at Auburn, Cal.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia, and 59 Gold St., N. Y. Agent for Pacific Coast—Joseph H. Dorety, 527 Commercial St., S. F.

PENRYN

GRANITE WORKS,

G. GRIFFITH, Prop.

Penryn, Placer County, - CALIFORNIA.

The Granite Stone from the Penryn and Rocklin Quarries was declared by experts at the Philadelphia Centennial Exposition to be the

Best in the United States.

GRANITE FOR BUILDING PURPOSES, TOMBSTONES AND MONUMENTS.

In BLUE, GRAY and BLACK shades, supplied to order on short notice. Address,

G. GRIFFITH,
Penryn, Placer Co., Cal.

Arrears of pay and bounty to Union Soldiers reported on the rolls as deserters, Act of August 7th, 1882.

Pensions for all soldiers disabled in line and discharge of duty, either by accident or otherwise.

Widows of soldiers who died in the service or since discharged from any cause due their military service, are entitled to Pension.

Parents In cases where the soldier died, leaving neither wife nor children, the parents are entitled to pension.

Bounty. Thousands of soldiers are yet entitled to bounty. Send for blanks and see if you have received all due you.

Discharges. Honorable Discharges procured; also duplicates. Send for blanks.

Increase of Pension. Thousands of Pensioners are now entitled to increase. Send for blank and we will advise you.

Address, with two three-cent stamps,

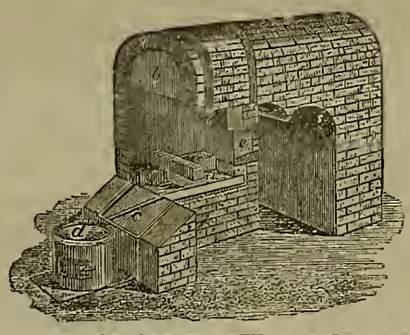
SAN FRANCISCO, SATURDAY, NOVEMBER 25, 1882.

VOLUME XLV Number 22

Lead Smelting in the Ore Hearth.

In the north of England, especially in the counties of Durham, Cumberland, Northumberland and Yorkshire, it is the practice to smelt lead ores, or, as it is here called, the "donso," in the furnace known as the ore hearth or Scotch furnace, and which consists of a rectangular chamber or cavity, *a* (see engraving), of some 24 inches in length, 12 inches in breadth, and from 22 to 26 inches in depth, which is lined entirely with cast-iron plates, the bottom being formed of one piece. The cavity or hearth is enclosed by a kind of arched hood, *b*, for carrying away the fumes, etc., produced during the smelting, while through the back of the furnace, and resting upon the back-stone (to be presently described), is introduced a tuyere, through which a blast of air can be maintained. At the front end of the cavity or hearth, *a*, is placed the work-stone, *c*, surrounded by a ledge on all edges except that nearest the hearth, while from top to bottom of this plate is cut a groove, gutter or channel, along which the lead flows into the lead pot outside as the hearth fills and overflows with metal. The work-stone inclines from the hearth, *a*, to the lead pot, *d*, and its top edge is about five inches above the bottom of the hearth. At the back of the furnace is placed the cast-iron prism or back-stone, *e*, upon which is placed a similar cast-iron prism, *f*, known as the pipe-stone, and which projects a short distance over the cavity of the hearth, while surmounting the pipe-stone is another cast-iron block, known as the upper back-stone; and along the sides of the furnace, resting upon the hearth bottom, are placed two prismatic castings or bearers, *g*, on which rest the extremities of the front prism of cast-iron analogous to the back-stone, but which is known as the fore-stone, each extremity of which is received between two cast-iron blocks placed upon the bearers of each side, and known as "keystones," by moving which backward or forward the forestone can be moved in the same direction. At the sides of the furnace, at the level of the keystones, is an opening through the brickwork, through which the workmen clear away the slag adhering to the tuyere, and also introducing a peat before the nozzle in commencing and during the working of the furnace. The ore or bouse for smelting in this furnace is, at certain works, first calcined in a reverberatory furnace; at other work the ore is not calcined previous to the smelting, but is charged directly into the ore furnace for reduction.

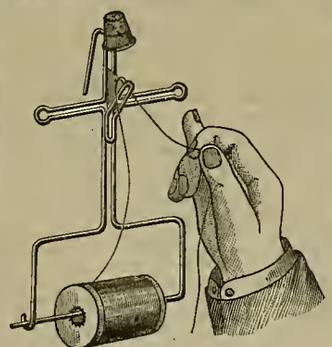
Supposing the ore furnace to be cleaned out from a previous operation, the rectangular chamber, *a*, is filled with peat, judiciously arranged around the hearth, since peat, with only a small portion of coal, constitutes the fuel of this furnace, which affords accordingly the only example of a metallurgical process in use in England, where peat is the fuel employed. The peat being properly arranged in the earth, an ignited peat is placed in front of the tuyere, and the blast is turned on, whereby combustion rapidly spreads throughout the furnace, upon which a little coal is added, and shortly afterwards a small portion of the partially reduced ore, mixed with slag and cinders, which remains upon the hearth at the end of each shift, and which is technically known as "browse" or "bronse," is thrown into the hearth, when, after the lapse of about half an hour, the temperature having in the meantime increased, and lead began to flow from the brouse, the contents of the hearth are stirred up, and a portion of the charge is thrown forward on to the work-stone, *c*, and any gray slag is separated, when the residue is returned to the furnace, and the regular working of the hearth succeeds; the charge being thus worked upon a bath of metal contained in the bottom of the hearth, and upon which the ore and fuel float. But the working requires a careful manipulation of the peats which are judiciously placed before the tuyere, so as to distribute the blast uniformly over the hearth, while the ore or bouse is added to the furnace charge in small quantities at a time, always introducing it on to that part of the hearth which appears hottest, when the work then proceeds regularly, with the introduction of peat fuel and bouse as required, the workmen stirring the charge with iron bars at intervals of about five minutes, whilst at intervals of about 20 minutes they throw forward a portion of the charge on to the work-stone, for the separation, as before, of gray slag, and to permit of the breaking up of any large lumps of bouse that may have collected, after which the bouse, with a certain quantity of coal and quick lime, is returned to the furnace, and a fresh supply of raw or roasted ore is placed on the top, while, at the same time, another workman introduces his bar into the furnace, and detaches any slag, etc., that may



ELEVATION OF THE ORE HEARTH, PARTLY IN SECTION.

have attached itself to the tuyere. Lead is now freely reduced from the ore, and collects in the bottom of the hearth, which it soon overflows, and passes along the gutter or channel in the middle of the work-stone into the kettle, or lead pot (*d*), which, when full, is skimmed, and the metal ladled out into molds forming pig lead. In a shift of from 12 hours to 14 hours the above furnace will yield about 2 5 tons of lead.

The method of manipulation detailed above is somewhat modified in different works; thus, after separating the gray slag from the work-stone, and breaking up any lumps of brouse, it is the



A USEFUL HOUSEHOLD DEVICE.

practice in some works (only if the latter shows a tendency to become pasty) to spread over it, before returning to the furnace, a little slaked lime in powder, and thereby prevent its clotting.

The temperature employed in the ore furnace or Scotch hearth is much lower than that employed in the Flintshire and other reverberatory furnaces, and the reduction of the ore is effected largely according to the reactions between plumbic oxide and sulphate with plumbic sulphide—the formation of oxidized products for effecting these decompositions being promoted by the exposure to the action of the atmosphere of the heated brouse upon the work-stone, in the manner described, while possibly a smaller proportion of metal may also be reduced by the action of carbonaceous matters upon the oxidized compounds of lead.

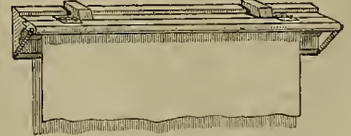
The ore furnace cannot be worked uninterruptedly, since it becomes too hot; to overcome which difficulty it has been proposed, as in the American hearth, to make the hearth-box bolow, and so cool it by blowing air around the hearth.

The ore furnace is applicable to the treatment of poor ores in districts where peat is abundant, and coal more or less scarce; but where coal is cheap and abundant, this furnace cannot be applied to the smelting of lead in opposition to the reverberatory furnace.

A Useful Household Device.

We illustrate herewith a combined spool and thimble holder and thread cutter, which has just been patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by A. M. Barrett, of Ione City, Amador county. The invention consists of a suitable spindle or shaft for receiving the spool, of a standard for supporting the thimble, of a cutter for severing the thread, and of a hook or pin for affixing the device in a convenient position. These are the results of a construction, as follows: A single wire is bent to form a cross above and an open base below, one end of the wire fitting into a hook on the other end at one corner of the base and forming the spindle for the spool. Upon the front of the cross above is soldered a wire, the upper portion of which is bent outwardly and receives one end of a small blade extending from the main piece. Upon the back of the cross is affixed a bent pin or hook which sustains the device and forms with the top of the cross a secure resting place for a thimble.

The engraving represents the vertical or central portion, having arms of a cross having an open base, at right angles. These parts are formed of a piece of wire bent double to form the center and arms. At the base of the center the wire extends in opposite directions,



BLAKE'S BILL POST.

thence downwardly where one end is bent to form a hook. The other end extends across to it and lies in the hook, thus forming a parallelogram, the base of which is the spindle, which may be released from the hook when necessary. To the center in front is attached a small piece of metal, shown as a bent wire, the upper portion of which diverges from the center wire. There is also a small cutting blade, as shown. A piece of wire is attached and bent down to form a hook or pin.

This device is intended to be secured to the garment of the person using it, in some convenient position by simply inserting the pin or hook. To insert the spool the end of the spindle is released from the little hook and the spool fitted upon it, after which it rehooks, and the thread may be drawn from the spool which is thus secured. The thread may be cut upon the blade above, and when it is necessary for any purpose to lay aside the thimble it may be fitted upon the top of the center. Its edge will pass down between the loose top of the pin and the back of the center, and be held securely from falling off. The cross arms and wide blade lend stability to the device, and cause it to lie in a convenient position. This little implement is useful to persons who do any kind of hand sewing. Its convenience and effectiveness, together with its small cost, render it a desirable article. Territorial and State rights in this device will be sold by the inventor.

Blake's Paper File.

Mr. H. H. Blake, of this city, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency a peculiar paper file or "bill post," the nature of which is shown in the engraving on this page. It consists of a stationary pad or stock provided with a groove and securing pins, adapted to be sustained from a wall, and of a swinging pad or stick provided with a tongue and holes to receive said pins, and hinged to the edge of the stationary pad with which it is held in relation by means of springs. The object is to provide a simple and effective means for holding a file of papers, or for securing posters, playbills, quotations, ship's manifests, etc., which are usually tacked or pasted on the walls.

It is particularly adapted for use in hotels, offices, saloons, barber shops and all public places where it is desired to exhibit such advertising matter without defacing the wall with tacks, or daubing them with paste. By its use the paper is not mutilated, nor can it be removed without first throwing back the clutch or fastening, which extends the entire length of the apparatus. If desired, any number of bills may be exposed at one and the same time, those having been placed in first being temporarily held in place by means of pins, properly arranged for that purpose. Finally when the clutch is brought down, all are firmly held in place by means of the tongue and groove clutch. Warren Holt, 413 Montgomery street, is the agent. Different sizes of this device are made

WASHING GOLD.—The squaws continue to sort over the old ore dumps and pick out the gold-bearing quartz and dirt. They do not find much of the stuff that Romeo said was worse poison to men's souls than any compound to be found in an apothecary shop, yet they do not complain, but go about their business with calm resignation. Some of these old women scarcely earn their salt; but 'tis no matter. The average Piute is happier than his superior white neighbor, and he knows it.—*Bodie Free Press.*

FROM 10,000 to 12,000 tons of salt have been gathered along the shores of Great Salt lake this season. There is a large surplus of common salt left over from last year, and this caused the gathering of a less amount than usual. The lake furnishes salt for use in all the silver mills of Idaho, Montana and Utah, and large quantities are shipped to Colorado and Nevada for the same purpose. The supply is unlimited, and the quality is in proportion to the care used in its manufacture.

THE CALICO MINING DISTRICT.—Travel on the Atlantic and Pacific railroad from Mojave to Calico mining district (the portion of the road thus far completed) began on the 13th instant. The track does not run direct to the mining district, but to a station a few miles distant, and passengers are taken in stages the rest of the way. Trains connect at Mojave with through trains from the north and south. The distance from this city to Calico is 462 miles, from Los Angeles 181 miles, and from Mojave 80 miles.

PARK CITY, UTAH.—Mr. Geo. Pierson is now acting as our agent and correspondent at Park City, Utah. He will send us notes from that vicinity, and we bespeak for him a pleasant welcome. We hope the miners of that region will help him all they can in obtaining information, and we hope, also, to see the names of many of them on our subscription books.

A NEW MEXICAN paper, called the *Pointers*, gives the following as the *bete noir* of the mining industry: "Distant Directors," "Stupid Superintendents" and "Misused Money." This is truth in a nutshell.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Park City Mining Notes.

EDITORS PRESS:—The injunction suits and cross suits on Pinyon bill bave been oompromised. The Pinyon, Climax and Rebellion bave consolidated, making 600,000 shares of $25 each; capital stock, $15,000,000, with Edward . PFerry President; R. F. Baskin, Vice-President; C. L. Hsines, Secretary; W. S. McCormick, Treasurer. Tbe Board of Directors consists of E. P. Ferry, R. F. Baskin, C. S. Haines, Artbur Brown, E. J. Travis, Wardis Thomas, D. C. McLaughlin, C. H. Whitaey and M. Kirkpatrick. This is a very strong company of men, well known for their euergy, capscity and ambition. Mr. E. P. Ferry is one of the representative men of the csmp, aud bas expended large sums of money in development of mines, building of mills and smelters, and unwearied euergy in building up tbe camp. To bim belongs much of the credit of having compromised the long, vexatious suits of the three mines that compose tbe splendid mining property now called the Crescent. Mr. Baskiu is well known for his loug, bold and courageous opposition to polygamy and dominant church rule, and as a very ahle mining lawyer. Mr. McCormick is a well known prominent hanker of Salt Lake, and the other members of the Board are well kuown and reliahle business men. Mr. Daly, the Supt., is an experienced miner, who will show what tbe mine is capahle of. Tbe output for the fragment of Oct., from the 11th to the close, the mine shipped 700 tons, 300 of which were worked at tbe Park smelter, the balance shipped to Salt Lake.

It has heeu claimed for five years tbat although we had the best mine in the world (the Ontario) it was a solitaire. I think we may fairly claim now tbat there is a little ore outside the walls of that vein. And if half I hear is true of veins tbree to five feet tbick, I shall bave mucb more to say soon, the development of the Crescent and other lodes of the bill be fully set forth. After examination reliable information will be solicited hy your correspondent, and carefully noted. Yours truly,

FORTY NINER.

Park City, Nov. 5, 1882.

Amalgamation.

Henry Moon, M. E., writes to the London *Mining Journal* on the subject of tbe sickening of mercury in gold amalgamation:

Without wishing to enter into the controversy between Mr. W. Crookes and Mr. T. A. Readwin about their respective claims to the sodium process of amalgamation of gold and quicksilver with tbe object of getting gold out ot quartz, I must say tbat I think very much is made of a little. Tbis sodium, as well as many other processes, seem, according to the fancies of their advocates, to be necessary to prevent wbat they call flouring of the quicksilver. My experience in this matter points to ouly one cause of the quicksilver flouring, and that is grindiug it witb quartz, or producing tbe same effect either by stamping it in the hoxes, or too violent action in the amalgamating box or cradle. With quicksilver as pure as it could be msde by distillation I have secured gold tbat was so fine that it could be squeezed through a wash-leatber with quicksilver, altbough the stone tbat bad been crushed, and from which the gold was extracted contained copper, lead, in which wae a portion of silver, sulphur, blende aud pyrites, not one of these metals interferiug in the slightest degree with the action of tbe amalgamating process hetween tbe gold and the quicksilver as ueed in my simple amalgamator. I believe, however, if the ore had been roasted before heiug crusbed the effect might have been different, and for thie reason I prefer to crush the ore as found. It is highly desirahle that if possihle a decision should be arrived at on this subject, and with a view to test tbis I sball be very glad to try conclusions with Mr. Readwin, or any other person who has either invented or improved any amalgamator, hy trying one of mine alougside of it, the stipulation being tbat the crushed quartz ehall in all trials he takeu from the same heap. That in each trial each machine shall bave 5 dwts. of tbe finest gold put into the quartz before working, aud on tbe whole of the quartz being treated the gold sball be sought for in the quicksilver. Of course it is necessary that there should he no gold in tbe quartz but tbe 5 dwts. put in. In my case I will use nothing but pure quicksilver, hut all or any oue else sball be at liberty to use any one or as many ingredients as they like. If this could be carried out in the presence of witnesses some degree of truth might he arrived at.

PNEUMATIC TUBE FOR PHILADELPHIA.—The Post Office Department is consideriug the feasihility of putting in very large pneumatic tubes for the Philadelphia Post Office, connecting it with the mail depots in the city. The object is to avoid the slow transference of mails from trains hy coaches to the central office. No steps as yet have heen taken in regard to actually putting the plan iu operation.

The Denver Exposition—No. 14.

[Editorial Correspondence.]

Coming back from the Black Hills, where our last letter left us, to the Union Pacific, at Cheyenne, we lind ourselves in the extreme southwest corner of the Territory of Wyoming. Tbis Territory has not yet msde itself generally known as a producer of miuerals, either precions or otherwise. It does not appear at all in the Miut reports as either a gold or silver producer. But

The Wyoming Exhibit

At Denver told a story ahout which tbere can be no mistake. As soon as tbat expositiou was decided upon, Gov. J. W. Hoyt issued a proclamation calling attention to the importance of making a creditahle exhibit on tbat occasion of the resources of tbe Territory. The Legislature had adjourned, and tbe Governor and his friends bad to rely wholly upon private efforts and resources to accomplish the object. How well he succeeded was shown hy tbe remarkahle and reslly heautiful display of ores, miuerals and otber resources and products which were placed on exhihition. The exhibit itself was a

Monument of Manly Pluck,

Taste and industry. No other such varied display was made in the huilding. It was a life study from nature. It was a grand exhibit of telling hut mute eloquence, and one that will uever he forgotten hy the thousands of visitors who daily thronged tbat psvilion. The Governor did not feel tbat his work was doue when tbe display was collected and forwarded, but he followed it to Denver aud persoually saw tbat notbing was left undone in arraugements to make it effective. He did not stop even with that, but, by iuvitatiou, took his stand upon the platform of the Graud Opera House, and made one of the most eloquent and telling speeches of tbe many that were delivered tbere and at tbe exposition huilding. His speecb was replete with facts in regard to tbe grandness of the scenery and wonderful possibilities of the Territory over which he has been plsced as Governor. The people of Wyoming may well hs proud of a Governor who tskes so much interest to huild up and sustsin their industrial interests.

Wyoming's Elegant Pavilion

Occupied a central and quite conspicuous position. On the four corners were huilt up, to tbe hight of about 10 ft., monuments of her four great industries—tbe one was a display of her rich hemstite ores, now being utilized by the Union Pacific rolling mills. Another consisted of gold and copper ores, from mines whiob are just heing opened in various parts of tbe State. The third was an artistic display from her 15,000,000 acres of the finest timber land on tbe continent. The fourth consisted of an immense square column, huilt up with wonderful cubes of sulphate of soda, from a 15-foot hed of that substance in tbe Sweetwater valley. On tbe several sides were arranged glass cases, containing elegant cahinet specimens of gold, silver, copper aud iron ores; also, chunks of bi csrhonate of soda, from vast deposits, alabaster and gypsum, mica, asbestos, and many otber natural products of economical snd iudustrial value. In the center of the space stood a huge column of coal, made up of large cubes, representing quite a numher of heavy veins of tbat mineral, varying from 4 to 40 ft. in tbickness. From tbe top of this column festoons of red and wbite hunting, drooped gracefully dowu to the more modest columns at the corners, and the cases arranged upon either side, thus forming an elegaut and appropriate canopy over the entire exhihit. Inside the square, and tastily arranged upon the tables, were other exbibits of a similar nature, tbe chief among wbich was a section of

A Fossil Tree of the Geode Class,

Decidedly the most elegant natural production in tbe entire huilding. Tbis foseil wae about 2 feet in length by 14 inches in diameter. It was hollow, showing a rim ahout two inches tbick of agatized wood, with a half-iuch tbickness of hark, showiug the grain of hoth wood and bark very distinctly. Tbe interior was elegantly studded with crystalline formations, the whole presenting to tbe bebolder one of the most heautiful specimens of the kind ever seeu. Stalactitee of aragonite, heautiful formations from the numerous caves ahout Green river, were also shown, as well as prehistoric skulls and petrifactions of turtles, fishes and otber small animals of hy-gone ages. Ornamental fronts graced aud beautified the two principal entrancee to tbis tasteful aud artistically arranged exhibit, whicb, in its entirety, reflected tbe higbest credit not only upon tbe people of the Territory, but also upon Gov. Hoyt and his most efficient co-lahorer, Prof. Bailey, wbo was untiring in his endeavors to make it not only attractive, but useful and inst uctive as well.

Copper in Wyoming.

During the past year some important discoveries have been made near Laramie in the way of oopper. A very large nnmher of claime bave been located, and quite a numher have already heen pretty thoroughly prospected. The locality of these miues ie embraced within a radius of 30 milee from a point on the North Platte river, about 15 miles west of old Fort Laramie. "Forty-uiners" aud others who made the trip across the plains from 1849 to 1853 will readily call to mind thie location. Fort Laramie was a great stopping point at that time, where nearly every company laid over for a few days to rest and recuperate their stock. No one who passed that way can have forgotten the rough red hills which were encountered a few miles this side of Laramie. Well, just tbere, among those hills and mountains, from 10 to 40 miles tbis side of the old fort and on tbe nortb side of the river, have been found wbat are supposed to be some of tbe richest copper mines this side of Lake Superior. Tbe mineral appears in every known variety of the ore. Several towns have already heen laid out, the chief of wbich is known as Hartsville, which is directly upon tbe old emigrant road, upon the north side of tbe Platte. Tbe locality was formerly known as "Indian Springs," and was a favorite halting place for tbe early emigrants.

No other continental pathway has such a romantic or tragic history as those old emigrant roads upon hotb sides of the Platte, which of late years, nntil now, have been used only by cowboys and rauchmeu. No emigrants ever turned hack after passing two days' journey this side of Laramie. Many, bowever, lost their last spark of courage after entering, late in the season, these rugged, harreu bills. The writer, while crossing the plains in '49, met quite a number wbo turned hack from there, hut he never met one on the back track who ventured beyond, for the reason that the danger of return was fully as great as anything could he ahead.

The prominent features of the formation here are red porphyry, mica-schist, quartzite and limestone. Red hemstite iron ore is also very ahundant, and gives a decidedly red coloring to the whole country. The veins wbich are found in tbe contsct liue between limestone and tbe quartzite or schist are generally rich in carbonates. All the ores tbus far brought up are easily worked, hut the more refractory ores will undoubtedly be met with in depth. We understsnd that a California water jsoket smelter is now in process of construction to treat the ores of tbis region.

In Extent and Resources

Wyoming may be favorably compsred witb almost any State in tbe Union. It embraces a territory as large as New York, Pennsylvania and New Jersey combined. The numerous eccentric chains and spurs of mountains, much hroken up and interrupted by broad stretches of valley and plain, hesides heiug clotbed, many of them, with splendid forests of pine, fir and spruce, are vast storehouses of mineral wealth, which may he briefly summarized as follows:

Gold—In tbe Wind River, Seminole, Shoshone, Medicine Bow, Laramie and other ranges of mountains.

Silver—In tbe Snowy Rsuge, at tbe sources of Green River, in tbe mountains near Cummins City, and in the hills on tbe Platte river above Fort Lsramie.

Copper—At many places in tbe Medicine Bow, Seminole aud Ferris mountains; near Rawlins, and in the Laramie rauge, both north and south of the railway.

Iron—Immeasurable in amouut, in tbe Laramie range north of Laramie City, and elsewhere.

Graphite, near Lsramie City; sulphur, in large bodies, near Evanstou; soda, botb sulphate and hi-carhonate, in the Sweetwater valley, of which the United States imports annually to the value of $7,000,000; salt, at the western foot of the Black Hills; slso, magnesis, kaolin, fire clay, petroleum, etc.

Coal measures of vast extent, with veins of 4 to 40 feet in thickness, and of excellent quslity, along the line of the U. P. Railway, on the Oregon Sbort Line, in the Seminole region, in the regions east of tbe Laramie range aud of tbe Big Horn mountains—in fact, cosl iu nearly every section of Wyoming.

Agricultural Resources.

In addition to her mineral wealth and 15,000,000 acres of forest growtb, Wyomiug poeseeses over 7,000,000 acres of irrigable valley lands, exceedingly fertile, and producing the most nutritions grasses, aud inviting the tiller of the eoil with promise of bountiful crops of wheat, barley, oats, potatoes and other vegetables, and all the hardy fruits of the tempsrate zone.

Wyoming probably possesses tbe hest sbeep and cattle ranges in the United States. Her plaine and valleys already aggregate over 700,000 head of cattle, 40,000 horses, and over 450,000 sheep. Her Territorial Stock Association is the largest and strongest in the Union, if not in the world. It represents over $15,000,000 of capital. The Union Pacific railroad passes through tbe entire length of tbe soutbern part of the Territory, from wbicb branches are projected, and will soon he constructed, to various points in tbe interior, and through Wyomiog into the growing Territory of Montana.

Climate and Scenery.

The climate of Wyoming is, at least in one particular, peculiar to itself, for, notwithstanding the high altitude of a large portion of the Territory, the winters are much milder than other portions of the Union at low altitudes, and in tbe same latitude, while the severity of the summer sun ie greatly modified by tbe cool breezes which almost always prevail duriug that season. The magnificence of its scenery has heen the theme of every writer who has visited the interior of the Territory. All readers know that the Yellowstone park hafiles description, and there are numerous other localities where the scenery is quite as heautiful, hut not on so grand a scale. In short, Wyoming has no doubt a hrilliant future. She is, in fact, a vast empire of mineral and general wealth, which needs only popnlation, capital and market facilities to make her a promiuent factor in the world's commerce.

W. B. EWER.

New Reduction Works in New Mexico

From tbe *New Southwest* we take tbe following: A company has recently heen organizsd at Silver City for the purpose of erecting works for the reduction of ores from the mines of tbe neighborhood. Work has already heen commenced upon the millsite of tbe Massachusetts and New Mexico Consolidated M. Co., in tbe upper part of tbe city, whioh bas been leased by the new company for a long term of years. The gentlemeu composing tbe company are all well known in mining oircles. Amoug tbem we may mention Col. Paschal R. Smitb, of tbe Valverde Mining and Smelting Co. at Pascbal, President; Robert A. Jackson, late chief engineer of the M. and N. M. Co., General Manager; Walter Holberton, of the Royal (Britisb) School of Mines; J. B. Norton, a sucoessful millwright, formerly of Golden, Col.; Jobu Powers, late of Hill's reduction works, at Denver; Mr. Gsorge Lloyd, of Colorado, a well known builder of reverberatory furnaoes, and others. Tbe company is backed hy an ample capital, and this fact, combined with tbe professional skill and practical experience of tbe gentlemen named, would seem a suffioient guarantee of success. The works, for the present, will consist of one reverberatory furnace and one water jacket, witb a capacity of 25 tons each daily. To tbese will be added as the wants of the business require a 10 stamp mill (for whioh the plans are alrsady drawn), concentrators, and other furnaces if needed. A 150-horse power engine, with boilers, is now in place; orusher and Cornish rolls will also be in positiou shortly. A large amount of huilding material has been purchased from Black & Co. and Welden, of this city. Grading for the site of tbe smelters and stamp-mill is well advanced, and the ghostly ruin of the Massachusetts and New Mexico Co.'s mill has disappeared, giving place to a soene of husy activity, under the supervision of Messrs. Jackson and Norton, of tbe new company. An opportunity will soon be given to the miners of tbis vioinity to dispose of their ores at satisfactory prices or to bave them worked on liberal terms, as tbe company will be prepared to bandle any and all of tbe various kinds of ore in Grant county. It is to be hoped tbat tbe erection of these works will stimulate mine owners to tbe development of tbe many good properties now lying idle at our very doors, and to an increased production of the precious metals scattered so profusely in our midst. Tbe well known abilities and high character of tbe gentlemen at the head of this new enterprise should, as it doubtless will, command tbe confidence of our miners and mine owners, and they should in every possible way encourage tbem in their endeavor to supply a want long felt in tbis county. Of one thing the public may feel assured: the Silver City reduction works have come to stay; the word "fail" is not in their vocabulary. All tbey ask is tbat tbe ores be forthooming at the proper time; the company will take care of tbe rest. Our mining men should see to it that the reduction works are well sustained in the effort to make of Silver City the mining center of tbe southwest.

Prospects in Atlanta, Idaho.

Captain James Baxter came in from Atlanta Saturday night. The late storm has been very severe in the Atlanta mountains. The snow is from four to six feet deep on the summit between Rocky Bar and Atlanta, but is shoveled out for pack trains to pass over. There is no flour or provisions worth speaking of in Atlanta, and it will hardly he possible to get enough in to feed tbe people tbis winter. There is no grain to feed quartz teams, and hauling is suspended, and the mills have shut down. Nicb. Johneon's team of 30 animals, loaded principally with potatoes, was on tbe way over from Rocky Bar, and Kossuth's team of about as many more animals was at Nichol's toll-gate, loaded with flour, groceries and general merchandise for Atlanta, but unless a great deal more is got in, half the people will have to leave Atlanta to winter. And Rocky Bar is nearly as bad off for provisions. The miners are looming up in splendid shape. Three new 20-stamp mills for Atlanta have been purchased, and will be at Kelton, or the terminus of the Oregon Short Line next spring—one for the Lenora mine, one for the Atlanta mine, and one for tbe Tehoma mine. All these mines have been worked by their respective companies the past summer, and have opened up in splendid shape, each showing ore enough to pay for the mines and mills and a large surplus of ore on the dump. Tbe Last Chance mine, worked by Captain Mat. H. Graham, paid—as long as they could get the ore to tbe mill—$800 per day, hut they had to shut down with 100 tons of ore on the dump, that would yield $100 per ton, and could take it out and run all winter if there wae any feed in the camp to keep the teams running. The early storms have closed them in without supplies, and a great deal of work will he suspended tbie winter, hut mining operations will he started up next spring with unprecedented vigor and prosperity. Twenty-five thousand dollars will be put up hy five companies to huild a wagon road down tbe Boise river to this place, and Mr. Pettit will purchase a portable saw-mill and take charge of the work and complete it hy the time the railroad is here. Captain Baxter came down to talk with his company hy telegraph, and secure supplies, if possible, and will return in two or three days.—*Idaho Statesman.*

MECHANICAL PROGRESS.

The Rolling of Steel Ingots With Their Own Initial Heat by Means of the "Soaking Pit" Process.

At the recent meeting of the British Iron and Steel Institute, Mr. John Gjers, of Middlesborough, England, stated that by the means to be presently described below it is now extremely easy and practicable to roll a steel ingot into a rail or other finished article with its own initial heat, without the aid of the hitherto universally adopted heating furnace. It is well understood that in the fluid poured into the mold there is a larger store of heat than is required for the purpose of rolling or hammering. It has, no doubt, suggested itself to many that this heat of the ingot ought to be utilized, and, as a matter of fact, attempts have at various times and in different places been made to do so. Hitherto, however, all such attempts have proved failures, and a kind of settled conviction has been established in the steel trade that the theory could not possibly be carried out in practice.

The difficulty arose from the fact that a steel ingot when newly stripped is far too hot in the interior for the purpose of rolling, and if it be kept long enough for the interior to become in a fit state, then the exterior gets far too cold to enable it to be rolled successfully. It has been attempted to avoid this difficulty by putting the hot ingots under shields or hoods lined with non-conducting material, and to bury them in non-conducting material in a pulverized state, for the purpose of equalizing the heat throughout the mass; but all these attempts have proved futile in practice, and the fact remains that the universal practice in steel works at the present day all over the world is to employ a heating furnace of some description requiring fuel.

Mr. Gjers introduced his new mode of treating ingots at the Darlington Steel and Iron Company's works in Darlington early in June this year, and they are now blooming the whole of their make, about 125 tons a shift, or about 500 ingots every 12 hours, by such means.

The machinery at Darlington is not adapted for rolling off in one heat; nevertheless, they have rolled off direct from the ingot treated in the "soaking pits" a considerable number of double head rails, and the experience so gained proves conclusively that with proper machinery there will be no difficulty in doing so regularly. The quality of the rails so rolled off has been everything that could be desired, and as many of the defects in rails originate in the heating furnace, Mr. Gjers ventures to predict that even in this respect the new process will stand the test.

The process, as described by him, is as follows: A number of upright pits (the number, say, of the ingots in a cast) are built in a mass of brick-work sunk in the ground below the level of the floor, such pits in cross-section being made slightly larger than that of the ingot, just enough to allow for any fins at the bottom, and somewhat deeper than the longest ingot likely to be used. In practice the cross-section of the pit is made about 3 inches larger than the large end of the ingot, and the top of the ingot may be anything from 6 to 18 inches below the top of the pit. These pits are commanded by an ingot crane by preference, so placed in relation to the blooming mill that the crane also commands the live rollers of the mill.

Each pit is covered with a separate lid at the floor level, and after having been well dried and brought to a red heat by the insertion of hot ingots, they are ready for operation.

As soon as the ingots are stripped (and they should be stripped as early as practicable), they are transferred one by one, and placed separately by means of the crane into these previously heated pits (which Mr. Gjers calls soaking pits), and forthwith covered over with the lid, which practically excludes the air. In those pits thus covered the ingots are allowed to stand and soak until the excessive molten heat of the interior becomes uniformly distributed, or nearly so, throughout the metallic mass. No, or comparatively little, is able to escape, as the ingot is surrounded by brick walls as hot as itself; it follows that the surface heat of the ingot is greatly increased. After the space of from 20 to 30 minutes, according to circumstances, the ingot is lifted out of the pit apparently much hotter than it went in, and is now swung round to the rolls by means of the crane, in a perfect state of heat for rolling, with this additional advantage to the mill over an ingot heated in an ordinary furnace from a comparatively cold one, that it is always certain to be at least as hot in the center as it is on the surface, which is not the case when it is furnace-heated.

It is well understood that every ingot, when cast, contains within itself a considerably larger store of heat than is necessary for the rolling operation. Some of this heat is, of course, lost by passing into the mold, some is lost by radiation before the ingot enters into the soaking pit, and some is lost after it enters, by being conducted away by the brickwork; but in the ordinary course of working, when there is no undue loss of time in transferring the ingots, after allowing for this loss, there remains a surplus, which goes into the brickwork of the soaking pits, so that this surplus of heat from successive ingots tends continually to keep the pits at the intense heat of the ingot itself. Thus, if occasionally it happens that inadvertently an ingot is delayed so long on its way to the pit as to arrive there somewhat short of heat, its temperature will be raised by heat from the walls of the pit itself, the refractory mass wherein the pit is formed, in fact, acting as an accumulator of heat, giving and taking heat as is required to carry on the operation in a continuous and practical manner.

During the soaking operation a quantity of gas exudes from the ingot and fills the pit, thus entirely excluding atmospheric air from entering; this is seen escaping round the lid, and when the lid is removed combustion takes place. This gas is entirely composed of hydrogen, nitrogen and carbonic acid, so that the ingots soak in a perfectly non-oxidizing medium. Hence, loss of steel by oxidization does not take place, and consequently the great loss of yield which always occurs in the ordinary heating furnace is entirely obviated.

Mr. Gjers does not think it necessary to dilate upon the economical advantages of his process, as they are apparent to every practical man connected with the manufacture of steel.

The operation of steel making on a large scale will by this process be very much simplified. It will help to dispense with a large number of men, some of them highly paid, directly and indirectly connected with the heating department; it will do away with costly heating furnaces and gas generators, and their costly maintenance; it will save all the coal used in heating, and, what is perhaps of still more importance, it will save the loss in yield of steel, and there will be no more steel spoiled by overheating in the furnaces.

Plain Facts About Boiler Explosions.

In a recent article emanating from the Hartford Steam Boiler Inspection and Insurance Company, we notice some very sensible facts respecting causes that conduce to boiler explosions, and which we believe will warrant us in commenting on.

The writer remarks that the tendency to employ cheap and irresponsible men as engineers contributes largely to the occurrence of accidents with steam boilers. This is a fact that cannot be too strongly placed before users of steam. Such economy is of the "penny wise and pound foolish" order, as many have found to their cost when too late. Intelligent service at good wages is cheaper in the end than ignorant service as a gift.

Another active factor mentioned is the dangerous practice that prevails with manufacturers at times when business is pressing and orders are crowding them, of working their boilers up to their full capacity and more. The evils of this practice are seldom estimated at their proper magnitude, and to the serious straining and weakening of boilers from this cause many disastrous explosions may be traced, directly or indirectly. The extensive experience of the Hartford Company confirms these opinions in the most unqualified manner, as the following declaration will testify: "Experience teaches us that nine-tenths of the boiler explosions in the country are attributable to carelessness on the part of engineers, or to the capidity and avarice of the owners, who, to save the expense of additional boiler power, will order their boilers to be run at excessive and dangerous pressures."

Why Wood Joists are Safer than Iron in Case of Fire.—Wood joists are being used in the construction of the building on Walnut street, above Fourth street, in preference to iron to guard against danger in case of fire. Strange as such a statement may appear, it is a matter of fact that many New England builders contend that the wood joists, encased in plaster, are proof against any ordinary fire, and for many reasons are much preferred by them to the ordinary regulation fireproof iron joists. The joists are "stripped" on the outside, and over these strips irons are run, and on these the plaster is spread. The theory is that in an ordinary fire these joists thus treated will be fireproof, and only when the fire has reached such a fury that the building must go anyway will they be affected. Here comes in one of the advantages claimed for them. When a building is being burned by a furious fire the iron joists expand and crash out the walls and do other damage. The wood joists would simply be burned up without injuring the walls at all.

Size of Pulleys.—It is generally supposed that the larger the palley the better the belt will hold, or the less tendency there will be to slip. Independent of other considerations, this is not true. A belt traveling 1,000 or any other given number of feet per minute, all other things being equal, will slip just as readily running over pulleys four or even eight feet in diameter as it will over pulleys but two feet in diameter. Nor will it transmit any more power running over the large pulleys than it will over the small pulleys. The power that a belt will transmit is in proportion to the number of feet it travels per minute, without any reference to the size of the pulleye, provided, of course, the pulleys are large enough for the belt to take a good hold on. A belt cannot bend around and hug closely pulleys but a few inches in diameter.

SCIENTIFIC PROGRESS.

Velocity of Falling Water.—The mean or average velocity of a flowing stream is found by scientific experiments to be from .81 to .83 of the maximum velocity, or that in the line of the current. At half depth of the stream the velocity is .914, and at the bottom .83 of that at the surface. The average depth of flowing water is found by setting off the breadth of the stream into any convenient number of divisions, ascertaining the depth of each and adding these depths together; their sum being then divided by the number of divisions of the stream, the quotient will be the average depth. The area of the stream is obtained by multiplying the mean depth by the breadth. To obtain the volume of flowing water, multiply the area of the stream by the velocity of the flow in feet; the product will be the volume in cubic feet. The velocity of water in a canal should be proportioned to the character of the bed. To prevent the deposit of slime and growth of grass a velocity of about eight inches per second is requisite, and the mean velocity over a slimy bed should not exceed this limit. Over common clay it should not be more than six inches per second; over sand or small gravel, one foot, and on shingle or stony bottom it may range from three to six feet per second.

Sound.—The following various observations of sound have been carefully verified by an extended series of experiments: The whistle of a locomotive is heard 3,300 yards; the noise of a railroad train, 2,800; the report of a musket and the bark of a dog, 1,800; an orchestra or the roll of a drum, 1,600; the human voice reaches to a distance of 1,000; the croaking of frogs, 900; the chirping of crickets, 800. Distinct speaking is heard in the air from below up to a distance of 600 yards; from above, it is only understood to a range of 100 yards downwards. It has been ascertained that an echo is well reflected from the surface of smooth water only when the voice comes from an elevation. Other similar phenomena connected with the transmission of sound have been observed, but the results disagree, either from inaccuracy in the observations or from the varying nature of the circumstances affecting the numbers obtained. Such variations occur to an extent of 10% to 20%, and even more. The weather being cold and dry, or warm and wet, are the chief influencing causes. In the first place the sound goes to a greater, and in the second to a lesser, distance.

Progress in Geological Science.—Within the last 35 years all the principal features of the geography of our own vast interior regions have been accurately determined; the great fields of Central Asia have been traveled in various directions from Bokhara and Oxus to the Chinese wall; the half-known river systems of South America have been explored and surveyed; the icy continent around the Southern Pole has been discovered; the northwest passage—the *ignis fatuus* of nearly two centuries—has been at last found; the Dead Sea is stripped of its fabulous terrors; the source of the Niger is no longer a myth, and the sublime secret of the Nile is almost wrested from its keeping; the mountains of the Moon, sought for 2,000 years, have been beheld by a Caucasian eye; an English steamer has ascended many of the African rivers; Leichard and Stuert have penetrated the wilderness of Australia; the Russians have descended from Irkontsk to the mouth of the Amoor; the antiquated walls of Chinese prejudice have been cracked and are fast tumbling down, and the canvas screens that surrounded Japan have been cut by the sharp edge of American enterprise. Such are the principal results of modern exploration. What quarter of a century, since the form of the earth and the boundaries of its land and water were known, can exhibit such a list of achievements?

Determining the Color of Water.—There has been some difference of opinion as to the color of perfectly pure water, and a German journal says that Victor Meyer has been investigating the matter. He finds that the color is neither blue nor green, but a shade between the two. To demonstrate this he takes five glass tubes, 40mm. in diameter, and about 1½ metere in length. These are connected by means of rubber tubing, forming a tube 7½ metere long. Both ends of this tube are closed with glass plates fitted in metal sockets. The latter are furnished with brass nozzles for filling the tube. The tube itself is placed in an exactly horizontal position and covered with a black cloth. Upon looking through the empty tube the field of vision appears perfectly colorless, the cloth and the metal sockets preventing the color of the glass from exerting any influence. As soon, however, as the tube is filled with distilled water, an intense bluish-green color is observed.

The philosophy of preserving meat by smoke is not very well understood. Wagner says the heat of the smoke dries the meat, while the creosote coagulates the albumen substances, which, once coagulated, are thereby rendered insoluble, and capable of decay only after a long time. Smoke, moreover, contains some pyroligneous acid, and other creosote-like substances (oxyphenic and carbolic acids), which undoubtedly play an important part in this preservative action.

Some Phenomena Presented by Metals.—Among the interesting phenomena disclosed by the recent application of chemical tests and analyses to the different metals, is the fact, as appears, that iron is entirely non-volatile, while the phosphorus in it is volatile, if chlorine and sufficient heat be applied; lead is vaporized at red heat, and zinc about the same. Again, the telluride of gold ore is found to be impossible of smelting in ordinary cupola furnaces, because tellurium gives to gold the property of becoming volatile at a red heat, while gold itself is considered non-volatile at even a white heat, but it is found that chloria has the property of combining in a gaseous state with gold at a heat of 4,000 degrees, rendering it so volatile that its vapors can be carried into a proper condenser and there condensed the same as oil vapors are condensed. It is found by furnacemen that silver and lead, when smelted together, are carried off to the extent of 10 to 30 per cent., even at ordinary furnace heat. By several analyses of Duryee's furnace slags from gold and silver ores, it was found that the metals were all vaporized down to 10 or 50 cents per ton of ore.

Phosphorus in Charcoal.—According to the *Engineering and Mining Journal*, Swedish engineers have noticed that the quantity of phosphorus in the pig manufactured with charcoal is larger than that in the ore and fluxes, even assuming that all of it had gone into the pig. Jansen found that when he melted ore in crucibles, the metal obtained ran lower in phosphorus than the pig obtained from the same ores. Sernstrom, in 1881, made some analysis of charcoel, the results of which seem to lead to the conclusion that the excess is due to that fuel. Two general samples were carefully analyzed, from the ashes of which were obtained respectively, 1.64% and 0.65% of phosphorus. This percentage represented respectively 0.0167% and 0.0054% of phosphorus in the coal. This is quite a new and unexpected fact, and one very important in the manufacture of iron.

The Future of Niagara Falls.—Prof. Tyndall gives some interesting views in regard to what he terms the "proximate future" of Niagara. At the rate of excavation assigned to it by Sir Charles Lyell,—namely, a foot a year—Prof. Tyndall says that 5,000 years or so will carry the Horseshoe falls higher then Goat island, and, as the gorge recedes, it will drain, as it has hitherto done, the banks right and left of it, thus leaving a nearly level terrace between Goat island and the edge of the gorge; higher up it will totally drain the American branch of the river; the channel will become cultivable land. The American falls will then be transformed into a dry precipice, forming a continuation of the cliffy boundary of the river Niagara, and lastly, at the place at present occupied by the fall there will be a whirlpool.

Formation of Alloys by Pressure.—W. Spring has shown that, when a mixture of bismuth filings, cadmium and tin, in the proportions necessary for the formation of Wood's alloy, is subjected to a pressure of 7,500 atmospheres, the mass thus obtained powdered and again subjected to the same pressure, a metallic block is formed which has all the physical properties of the alloy. Its specific gravity, color, hardness, brittleness and fracture are the same; and when thrown into water heated to 70°, it melts at once. In like manner Rose's metal was made by subjecting the proper mixture of lead, bismuth and tin to high pressure. If zinc and copper filings are repeatedly subjected to pressure, a mass resembling brass is finally obtained.

Hydrogen Gas in Steam Boilers.—M. Treve has communicated to the Academy of Sciences the results of his researches on the causes of some boiler explosions, with reference to the action of pressure of plates of zinc in boilers. The hydrogen liberated with galvanic action should theoretically maintain the boiling (after having started it), and so prevent explosion as a result of superheating; for this, however, the plates must be carefully kept clean. The author thinks it well to add the continuous injection of gas (preferable carbolic acid), and so incessantly prevent the superheating, which may be regarded as a sleep of the liquid.

The National Geological Survey.—Hitherto the surveye conducted by United States geologists have been confined to the Territories. Last winter Congress authorized the prosecution of such work at national expense within the lines of the States. Accordingly parties are now at work in North Carolina, Kentucky, Missouri and Arkansas, under the direction of the Chief of the National Survey, Professor Powell, obtaining data for a geological map of the entire country. Meantime the territorial surveys are not neglected, Professor Powell going to join the large party at work in Arizona and New Mexico. The Bureau of Ethnology has several parties at work in the Mississippi Valley.

The Telephone in the Fifteenth Century.—Leonardo da Vinci makes the following statement: When one is upon a lake, if he puts the opening of a trumpet into the water and holds the point of the tube to his ear he can perceive whether ships are moving at a remote distance. The same thing occurs if he thrusts the tube into the ground. Then also he will hear what is going on at a distance.

Mining Share Market.

There is nothing espscialy interesting concerning the stock market, as affairs connected therewith have been "slow" this week. On the Comstock within a few weeks a connection will be made between the Mexican and the Union Con. on the 2,900 level. This will he one of the most important connections of the year, not only as ragards ventilation and drainage, hut also on accont of the vast area of grond it will open np to exploration. The first thing in order will probahly he to look for the hody of ore left behind in the winze down from the 2,700 level of the Mexican and to explore the Union Con. ground under the point where the several streaks and hnnches of ore have been fonnd above.

They will ahont the same time he opeoing out on the 3,100 level of the Ophir and Mexican.

At the Chollar they have passed through one quartz belt, and are now in a more compact formation.

At Gold Hill a very considerable amonnt of low grade ore is now heing extracted and sent to mills for redoction.

Cedar Hill.

There yet remains in Cedar Hill, to he found by some fortnnate prospector, a deposit of gold-hearing quartz of great size and valne. In the early days a great amonnt of free gold was extracted from the southern slope of the hill hy sluicing. The ground then worked was exceedingly rich in gold. Not only was the dirt that was washed rich, hutthere were mingled with the dirt immense qnantities of fragments of quartz and quartz howlders that were rich, and in which free gold was plainly visihle. Some pieces of qnartz were found that contained wires of coarse gold of snch size that they held the rock togethr even after it had heen broken through with a sledge.

The parties who did this early work saved all the quartz that was washed out of the hill, and sold it for ahont $50 per ton to parties who themselvcs hauled it away to mills down on Six-mile canyon. The qnartz was taken just as it was forked out of the sluice boxes. There was no assorting, except to throw out from among the quartz snch granite howlders as were caught with it in the boxes. The parties who did this first mining on the side of the hill had hnt a small head of water, and did not attempt to wash any very great depth of grond. While they had shallow grouna they made hig pay, hnt when the hank hecame high they had too much top dirt to sluice off, and finally gave it up.

At the point where this sluicing was done there was a regular channel containing a deposit of earth and rock that had heen left there by the action of water. The place was probahly once the channel of Cedar ravine, now flowing a considerahle distance helow.

The ravine must have ont through a large qnartz vein on the side of the hill and gronnd ont the gold and qnartz, which it deposited in the debris helow in strata plainly to he traced. The stream appears to have made a hend into the hill at this point, as the deposit is of great hreadth.

A few years ago an attempt was made to work this deposit by the hydraulio plan, and thus eventually lay bare the vein from which came all the gold and quartz, hut as it was followed back into the hill it hecame very deep and there was so much harren surface dirt—earth and rocks that had rolled down the hill—that it could not he made to pay.

The pay dirt, and most of the qnartz that contains gold, lies in a stratum at the hottom that is hut a few feet in depth. This heing the case, we are of the opinion that the proper way in which to explore for the rich quartz vein or pocket is to drift hack into the hill along the hedrock. The drift wonld presently strike the wall of the channel which contains the gravel deposit, and hy turning and drifting westward along this wall the songht-for quartz deposit must eventnally he fonnd.

In making this search the dirt and quartz brought out of the drift wonld donhtless pay all expenses, and perhaps hig wages hesides. It would he necessary only once in a while to get water for three or four hours sufficient to wash up the dirt drifted out. But a small stream of water would he required, as it would he desirahle to save all the quartz—to sluice away nothing hut the fine dirt.

Could satisfactory arrangements he made with the Sierra Nevada Mining Company this would he a very good enterprise for some of our miners to undertake in these dnll times. Nothing could well he lost, as the dirt drifted out would donhtless pay expenses—wages—if it did not pay a profit, and should the vein or pocket sought for he found there wonld donhtless he a fortune in it.—*Virginia Enterprise.*

PATENT RIGHT AGENT.—Geo. B. Davis, an old and active resident of this State, has opened an office for the sale of patent rights on this coast, at No. 503 California st., San Francisco. Persons who wish to buy or sell patent rights can make a note of this. He has had considerable experience and marked snccess in his line of husinesa.

THE Montana mine, Bonanza, Idaho, took ont 60 or 70 tons of ore the past season, which averages $1,000 per ton in gold and silver. This ore lays at Bonanza, the company having failed to send it to market hecause transportation could not he had. They are working 12 men this winter, and will have $200,000 worth of ore to ship in the spring.

THE Lexington silver mill, at Butte, Montana, is doing fine work for the short time it has been in operation. The mill was started in Septemher, hut did not hegin running regularly nntil Octoher 1, and dnring the month the 40 stamps turned out hullion to the valne of $8,507.99. The ore in the mine averages $47.68 per ton in silver.

THE Salt Lake *Tribune* learns that the Holyoke mining company, at Bonanza Bar, on Snake river, Idaho, made a clean np last week, after having run three months, taking ont $6,000 in gold. It required the labor of four or five men to do this.

THE Ontario paid its 85th dividend on the 15th of this month. This makes a grand total of $4,775,000.

WOOD RIVER exchanges annonnce the departure of large numhers of miners for Salt Lake, with the intention of passing the winter.

ESTIMATES of the Utah bullion product this year are heing made among mining men, and vary from $10,000,000 to $13,000,000.

MINING SUMMARY.

The following is mostly condensed from journals pub-lished in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

BUNKER HILL.—Amador *Ledger*, Nov. 18: The suspension of all work at the Bunker Hill mine and mill is severe hlow to all interests in that section. It appears thst for the last four months the yield of bullion has not been sufficient to meet the working expenses. The ore bas been plentiful enough, but the quality bss been poor. Consequently the company fell in arrears in the payment of the wages of employees, until the total liabilities aggregate hetween $30,000 and $40,000, including some debts in san Francisco. In this state of affairs the msnsger in San Francisco felt disinclined to continue operations with the prospect of running deeper in debt, until the principal stockholders in the Eastern States had been consulted. Word was therefore sent up to close down. After considerable deliberation among the workmen as to the best method to secure the payment of wages due them, it wss finally decided to file mechanics' liens. Accordingly, hetween 40 and 50 of the men repaired tn Jackson Friday morning of last week, and recorded liens to the extent of about $18,000. This action, naturally enough, brought other creditors to the front. Several business men, to whom the company was also indebted, started suits, and attachments were issued thereon. Saturday morning the attachments were served, and George Dnrham, of Jackson, wss placed in charge as keeper. These clsims will aggregate $3,000 or $4 000. Other creditors now threaten to force the company into insolvency unless these attachments are di solved. Thus the matter stands at this writing. Whether the company will pull through the difficulty and resume operations is problematical. The general impression around Amador is that work will resume ere long. The Bunker Hill has been a remunerative property for several years past, until the almost harren ore of the past four months was encountered. Lately the shaft bas been sunk 200 ft, and in this distance no prospecting operations whatever have been done. It is not reasonable to think that the mine will be abandoned without at least sscertaining the character of the ledge at this depth.

Downs.—The mill was expected to start up tbis week. It will be remembered that in sinking the new shaft the ledge was struck 50 ft sooner than was anticipated. The last 50 ft, therefore, was sunk on the ledge, and this has turned out a large pile of ore, ready for milling. The rock is reported to be of good quality, and there is no douht that this prominent mine will rival its best days in the surrender of treasure. Building a track from the new shaft to the mill is what has kept the mill frnm starting up ere this. The work is now about completed.

MISCELLANEOUS.—The Volcano big tunnel company have commenced operations. The water supply is insufficient to keep the claim going steadily, but hy storing it in reservoirs they manage to secure enough to run a portion of the day. . . . A clean-up of the crushing of rock from the Jackson mine was made recently at the Moore mill. We have not been able to ascertain the amount realized. The amalgam was taken below immediately, and whether the rock yielded in paying quantities or not we have no means of knowing. The mine continues work as usual. . . . . The Moore mill is at present running on ore from Morgan's claim, in Murphy's gulch. It is reported that the plates are looking well, and that there is plenty of ore in the mine.

CALAVERAS.

MURPHY'S.—Cor. *Mountain Echo*, Nov. 18: Our mining interests have not suffered or been neglected during the past weeks of political excitement. Some, at least, have improved wonderfully in richness—notably the O. K. Rich specimens from this mine, yellow with the precious mineral, are daily shown—proof that we have mines and mineral rich enough to satisfy the utmost skeptic. Soublett & Dodge, the owners, have considerable ore on the dump, of high grade, and are now making efforts to have reduction works erected on their mine. . . . . The Boston Co.'s mines—Ore Plata, Red Wing, etc.—are looking as well as ever, and work under the efficient management of Mr. Morse, the superintendent, is being vigorously prosecuted. In addition to the group of mines being worked in this district by the company, it bas lately commenced operations on a mine in Eho that is rich in promise. A number of tons of ore bave been worked from it by its process, that yielded bandsomely. . . . . The new mill on the Red Wing is fast approaching completion. At no distant day the whistle from its engine will herald the morn nf a new and successful era among us in this mieing venture.

INYO.

SHERMAN.—Inyo *Independent*, Nov. 18: It is said a complete outfit—machinery, lumber, etc.—for s 10-stamp steam silver mill is now en route from Mojave to the mines at Sherman district, in the Slate range. This is the Reilly-Ely operation, and so close is the corporstion that no definite details can be obtained regarding its plans.

MARIPOSA.

A FIND.—Mariposa *Gazette*, Nov. 18: The Bandereta mine of P. P. Mast & Co., 8 miles above Coulterville, bas recently struck a "find" in the 1600 tunnel. Its superintendent, Charlie L. Mast, is much elated with the prospect.

THE HAMBIDGE & GONGAL.—This old mine, above Coulterville, owned by Francisco Bruschi, bas lately run into a bonanza, with the 500-ft tunnel. The vein is large, and the rock assays hig pay to the ton. Bruschi & Son expect soon to get back some of that $25,000 or $30,000 invested in quartz during the past 10 or 15 years.

THE "TOM BYRD."—The Tom Byrd vein is said to be a big thing. Tom had his pockets full of the rich ore, exhibiting it on election day. Whenever bis beans, flour and tobacco runs short, Tom goes for bis mortar, and in a few hours pans out sufficient to give another order for a month. He says it is as good a bank as be wants, so long as he is the cashier and director.

THE REED TALC.—Brother Reed, of the Reed Talc mine, near Coulterville, says bis mine is all that ever was anticipated; but tampering with new processes and experiments for extracting and saving gold will not pay, except the mine is nearly all gold, and a wide vein at that. This Talc mine bears gold sufficiently to pay well, whenever the proper process is ascertained for saving the gold.

THE NO. NINE.—The No. Nine (Yosemite mine), near Hornitos, with its 30-stamp steam mill, keeps well up to the standard of success and prosperity. In all its departments it employs and creates employment for at least 126 men, many with families. One of its most important branches is the Mount Gaines vein, from which is taken rock of high character, and transported some 4 miles to the Yosemite mill. This valuable group of mines consists of the No. Nine Pool and Mount Gains, all owned by Mr. Hulling, an Eastern gentleman, who has accumulated wealth from oils in Pennsylvania, or one of the oil-producing States. He is a man of remarkable activity and enterprise, and is, we understand, entertaining one of the most gigantic mining enterprises to be constructed in this portion of the State, which will probably cost a million or a million and a balf of dollars.

THE HITE.—This celebrated mine, after undergoing a power of extraction for nearly 20 years, is simply taking a rest. Some 2 years ago it changed its private ownership to that of an Eastern company, which has become mixed with other and various complications not due to any shortness of the Hite mine. Branches of business are often extended too far, so that when one or two fails it affects the whole and often creates a general disaster, as is probably the case with the Hite mine.

MONO.

BODIE.—*Free Press*, Nov. 21: As winter draws near work in the mines of this district does not diminish in the

least. A very large force of men is employed in the Standard, Bodie and the Noondays, and the chances are that there will be no let up during the coming winter. The upper levels of the Standard continue to yield large quantities of fair ore. The Bodie is also showing up well. The developments in the Goodshaw are promising. Tioga Con.'s shaft is being sunk, and no doubt crosscutting will be resumed at no late day. There is no change in the appearance of Syedicate, and the Bodie Tunnel locks well. Work in the Noondays is advancing rapidly.

STANDARD CON.—There were extracted and shipped to the mills 1,385 tons of ore. The bullion shipment amounted to $15,717.72. The east crosscut, 1000 level, has been run 14 ft since last report; total length, 1,092 ft.

ORO.—During the past week the 520 winze, south stope, has yielded 32 carloads of milling ore. The vein is about 2 ft wide. Three carloads of good ore were extracted from below the 440 level stopes. The vein is now soft, and it requires much timbering

BODIE CON.—During the week ending the 18th, 153 tons of ore were hauled to the mill and 109,753 tons were crushed. The average value of the ore crushed was $93.34 per ton. That of the tailings was $12.94. The bullion shipment was valued at $11,050.49. There were 225 carloads of ore hoisted, 28 of which were from the 740 level of the shaft, and 197 cars from the 640 incline level and the workings below it.

RED CLOUD CON.—The shaft is sunk to a depth of 860 ft, 11 ft having been sunk the past week The ground breaks well. The water has only increased slightly since last report. The north drift, Red Cloud vein, 700 level was extended 12 ft during the week; total length, 163 ft. The south drift, same drift, measures 179 ft.

NORTH NOONDAY.—The north drift, 325 incline level, was lengthened 14 ft during the week; total length, 209 ft. The vein is large, and is looking very well. The incline is 382 ft below the 542 level. The usual quantity of ore is being sent to the mill.

NEVADA.

A REVIEW.—*Foothill Tidings*, Nov. 17: Our mining men are all very busy, and are exceedingly hopeful, for the outlook is very encouraging indeed. The enterprise which the Idaho M. Co. is about to consummate, in the way of running a ditch which will connect with the waters of the South Yuba canal, in order to bring water here for the purpose of running their machinery, has put a new stimulus on mining affairs, and is looked upon with the utmost favor by this community. The Idaho company has not fully decided to run the ditch, but we are informed by Mr. Coleman that the probabilities are that the ditch will be built. Surveys and estimates are being made for the prospective canal, and as soon as any definite arrangements are made we will endeavor to let the public know it.....The Idaho has its shaft down, and on Wednesday started to drift for the 14 level. It is impossible to tell what developments will be made in the new level when it will be opened up, but the indications are favorable for showing a good ledge.....The East Eureka, or O'Connor, which is in close proximity to the Idaho, has greatly improved of late, and much of the rock taken from the ledge in the drift shows free gold. The mill at the East Eureka has been idle for several weeks past, because of the scarcity of wood, but now a road has been built to the railroad, and wood has been obtained. The mill will start up on Monday.....The Imperial Company is busily engaged in putting up its mill, and it will be completed in a very short time. The ledge of the Imperial is very large, and, from indications, it promises a bounteous yield for the future. The mill will be run by water power.....The Gray Hound Company are still running their tunnel, and are now in about 220 ft. The ledge in the face of the tunnel is 2 ft wide, and is full of lead and sulphurets; occasionally a piece is found which shows free gold. There is quite a pile of rock on the dump, which will soon be crushed....There is no change in the New York Hill since our last report. The report from the San Francisco office has not been forwarded to this place, and in consequence thereof we are unable to give figures for the last month's run..... The Empire is still at work, with all the stamps in the mill running day and night. The Empire is employing a large number of men.....The Indian Springs M. Co. has been organized and stock has been issued. The company is operating near Indian Springs, and has a tunnel driven 80 ft. At 200 ft the tunnel will cut a large ledge, which has prospected well by the hand-mortar process.

PLACER.

THE OUTLOOK FOR QUARTZ.—Placer *Herald*, Nov. 18: In this region of country the outlook for the quartz mining industry is just now more promising than it has been in the history of Placer county. A number of very flattering developments have been made within a comparatively recent date; and with a view to the more systematic working of several of these, new housing works and new mills, and on a larger scale than usual, are either in course of construction or soon to be commenced. At the Belmont a large quantity of fine ore is on the dump, which is being added to constantly, and the ledge improves in prospect as the developments proceed. Already a considerable number of necessary buildings have been erected at the site of this mine, and a fine 20-stamp mill is under headway. At the Odd Blossom a large, new boarding-house and other necessary structures have been put up, and the erection of a new 20 stamp mill, we understand, is about to be commenced. On the Morning Star the owners are putting up new steam hoisting works. This ledge has paid well for some time, and in the bottom of the shaft the ore is equal to the best taken from the mine. The Mammoth ledge, a short distance south of Auburn, has fallen into new hands, who are arranging to commence work on a large scale. They contemplate this erection of a large mill, and other works in proportion. At the Muarica, Col. McCullough is working along without making much noise. He is making improvements from time to time, all calculated to facilitate the working of the lead, which go to show that he has confidence in the property. Near Bald Hill, Wm. Werry has a force of men on the Blue Lead, which shows a strong vein of good looking ore. Some of these mines have recently been purchased by strong companies, and much of the large capital used in their further development is from the outside. The purchasers in each instance are pleased with their respective bargains, and others are coming among us from day to day, seeking opportunity for investment. A spirit of renewed confidence pervades the entire community, and unless all signs fail, the coming summer will be one of great activity and life in the Auburn and Ophir mining districts.

SAN BERNARDINO.

CALICO NOTES.—San Bernardino *Index*, Nov. 18: On October 28th Robert B. Johnson bought the Sam Houston No. 3 mine from H. B. Stevens. He has been energetically at work on the same, and his labors have been rewarded with some exceedingly rich strikes He intends to sink a 100-ft shaft, and is down 12 ft. The pay streak is 3 ft wide, and on one side assays $40 to the ton, and on the other $70. In the center ore assaying $7,000 to the ton has been taken out. The ledge is regular and well defined, extending the whole length of the claim—1,200 ft. Its width averages 10 ft. The character of the ore is chloride. A ton of ore a day is being taken out. It is being sacked, and in about two weeks will be shipped to San Francisco. This mine is located between the Sam Houston No. 1 and the Blackfoot, in East Calico.

DRAGON NO. 1.—Messrs. Charles Morris and Wiseman are pushing the work on the Dragon No. 1 as fast as possible. They are drifting in the tonnel. The pay streak is 6 inches in width, and the ledge from 5 to 10 ft wide. They are taking out first-class ore.

TAY.—The Tay mine, one mile west of Calico, is being worked by Lowry Silver. They are 20 ft underground, running on the vein, which shows white spar carrying black metal and chloride. They are sackingsome ore to go to the arastras at Fish Pond.

TIGER.—Mecham & Blackburn have taken a contract to work the district assessment on the Tiger claim, belonging to Sam James and others.

CONSOLIDATED.—C. L. Mecham and G. F. Blackburn are working the district assessment on the Consolidated mine. A strong vein is coming in the tunnel, and the prospect is good,

SIERRA.

DAM.—*Mountain Messenger*, Nov. 18: David Moore and others have a contract for building a dam on Slate creek, below Scales, and expect to finish it this winter. .....The tunnel of Judson, Kingdon & Co., Poverty Hill, is in 2,800 ft, and will be used for drainage for the hydraulicking mines.....The Marguerite mine, of Sierra City, is about to put in a large pump and other machinery. It is now being hauled from Truckee as fast as the roads will permit.

NEVADA.

WASHOE DISTRICT.

OPHIR.—Good headway is making in the main south drift on the 2000 level. The joint Mexican winze is being sunk at the rate of 10 ft per week. The west dip of the stratification at the bottom of the winze still continues. Seams of quartz that are metal-bearing are frequently cut. Ore is still being extracted from the croppings and sent to the mill for reduction.

CHOLLAR.—The south drift on the 2600 level will be extended about 80 ft this week. The ground is porphyry, with seams and bunches of quartz. The course of the drift has been turned from due south to 16 degrees east of that point, in order to avoid a piece of wet ground.

SIERRA NEVADA.—West crosscut No. 1 is now out some 60 ft from the main north lateral drift. The formation as yet is about the same as in the drift. The crosscut is about the center of the 1,000 feet of ground now open for exploration. Nothing else of interest is being done in the ground at present.

MEXICAN.—The joint Ophir winze has been sunk 10 ft. The stratification continues to dip west. Promising seams of quartz are being cut. The northwest drift on the 2000 level will connect with the south drift from the Union Consolidated in about three weeks.

GOULD AND CURRY.—Owing to the delay (60 hours) occasioned by the overhauling of the hoisting engine last week, the southwest drift, 2500 level, was extended but 17 ft. This week, however, good progress has been made.

BEST AND BELCHER.—The water in the face of the drift on the north uprift, 2500 level, is decreasing. There was the same delay here during last week as at the Gould and Curry during the overhauling of the hoisting engine, but all is again going ahead as usual.

HALE & NORCROSS.—Good headway is making in the main drift on the 2000 level Seams containing some water are occasionally cut across, but a drain being now in, these give but little trouble, though they cause a temporary increase of heat.

CALIFORNIA.—The usual progress is being made in the joint Consolidated Virginia east drift on the 2700 level. There is no change of formation worthy of note. About the usual amount of ore is being extracted at the croppings.

UTAH.—Repairs to the incline are still being made. Meantime the drifts below on the 2500 level are kept in good repair, and work can at once be resumed thereon upon the completion of the repairs to the incline.

YELLOW JACKET.—No low-grade ore is being extracted at five different points in the old levels. It seems probable that a large amount of paying ore will be found in these old levels.

ANDES.—The winze is in a favorable formation of quartz and porphyry. Low-grade ore that will pay for working is being extracted from the south drift.

NORTH GOULD AND CURRY.—Ground in bottom of shaft hard. Some work at easing timbers has been done above. The ground shows some bunches of quartz that look wells.

CONSOLIDATED VIRGINIA.—Very good headway is making in the joint California east drift on the 2700 level. Other work about the mine is going ahead as usual.

ALTA.—The indications are that satisfactory arrangements will now soon be perfected for the running of the drain drift to the Sutro tunnel.

SCORPION.—The usual progress is making in the main east drift on the 500 level. The formation remains about the same as heretofore.

CROWN POINT.—A considerable amount of low-grade ore continues to be extracted and sent to the mills from the old lower levels.

BRISTOL DISTRICT.

SETTLED.—Pioche *Record*, Nov. 11: The Bristol company paid its indebtedness due to its late employees for labor in full on Monday. It will settle its entire debt as soon as Mr. Baldwin returns, who has gone to Carson to attend court. There are seven men employed at the Mayflower mine.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Nov. 18: The main drift on the fifth shaft level has advanced 20 ft during the week, the face to be same being in sulphurets of low grade. Crosscut No 2, on the same level, has been extended 16 ft, its total length being 32 ft. A winze has recently been started from the fourth shaft level, near the west end, which is now down 15 ft, and when connected with the main drift on the level below will complete the air connection and enable the prospecting of that part of the mine to proceed with greater energy. The crosscut from the main drift on the third shaft level is in very hard ground, but 5 ft having been added to its length since the last report; the total length is 106 ft. The outlook on the second shaft level is quite favorable, and the production is very good. The ore body in the stope, about 50 ft in length, from the first shaft level is now about 3 ft in width, with every prospect of extending upwards. The levels above the adit present very much the same appearance as last week. The ninth and tenth levels look promising, and continue their usual production. About 64 tons of ore are being extracted and sent to the mill daily. The bullion shipments amounted to $18,689.02 for the week ending on the 16th inst., and aggregate $34 529.56 on November account to the same date.

MOUNT DIABLO.—The east drift from winze No. 1, 40 ft above the bottom of the same, is in 36 ft, and shows 2 ft of 80 ore in the face. The west drift from this winze is in 35 ft, and it is showing ledge matter in the face, while the raise from the east drift, mentioned above, has developed a 4-inch ledge of ore assaying $70 per ton. On the east intermediate level, at a point above winze No. 4, there is a foot of $100 ore in the bottom of the drift. The west drift from the west crosscut in the eastern part of the mine, on the first level, has developed an 8-inch vein of ore assaying $70, in the bottom of the drift.

COLUMBUS CON.—The ore vein has been encountered in the crosscut to the north of the shaft level, the face of it now showing a streak of first-class ore, 12 inches in width. Drifting is in progress to the east and west from the winze on the shaft level. The east drift has developed a strong body of first-class ore, while that to the west is looking very favorable, and has 2 ft of low-grade ore in the face.

EUREKA DISTRICT.

PAUL PRY.—Eureka *Sentinel*, Nov. 17: Work on the Paul Pry mine will be resumed in a few days, under the supervision of Captain Tuller. It is an excellent property, and with the main shaft sunk deeper and connection made between it and the old workings, can soon be placed on a paying basis, if it is not already in that condition. Adams Hill is covered with valuable locations; not among the least is the Paul Pry.....N. H. Camp, a gentleman from New York City, who is interested in mining property in this neighborhood, paid a visit to the Geddes & Bertrand mill yesterday, accompanied by John McOrath and Frank Robbins. The object of his visit was to inspect the leaching process, with reference to converting the old mill at the Trench mine into one of a similar sort. We understand that the result of Mr. Camp's visit will be to start up work on the Trenchmine, and on the Rescue.

LEWIS DISTRICT.

MORNING STAR.—Lewis *Herald*; Nov. 15: South drift, third level, advanced during the week 12 ft; total distance from the incline, 127 ft. Have cut considerable water the last week in this drift. Mayo incline advanced during week 10½ ft; total depth below third level, 104 ft. The contractors have completed their contract on the incline. Will commence to raise from head of Mayo incline to the surface, a distance of 70 ft. When this is completed will move hoisting works and hoist through this incline. The ore in incline is 3 ft in width, and of a good quality. The ore in south drift is improving since last report. The ledge in north drift is very much broken.

BETTY O'NEAL MINE.—The boiler was got in readiness early Sunday night. The pumps were started and are doing good work; with the assistance of the bailing tank, the water will soon be reduced. Quite a number of improvements have been made in placing the machinery. A new and larger sheave has been placed on the gallows frame, and the building will be erected as soon as it is possible to do so. There is 60 ft of water in the shaft, and as soon as this is reduced the usual number of men will be set to work again.

MINERAL HILL DISTRICT.

STARTED WORK.—Eureka *Sentinel*, Nov. 18: The Christy M. and M. Co., represented by H. G. Catlin, manager, has started work on the mines recently purchased for them by him at Mineral Hill. This property includes all the mines there in fact, the whole hill—which was formerly owned by the Taylor and Austin Companies. Until recently the time has been occupied in opening the mines, repairing the 15-stamp mill and putting the water works in order, preparatory to a run. The mill has eight pans and a Stedtefeldt furnace. Mr. Catlin is confident that there is an abundance of ore that can be taken out with but little expense to run the mill for an indefinite period. The ore is tolerably free, and will not be roasted, as was done hitherto, as he believes the roasting does not justify the difference in percentage. The first run will be made on about 1,200 tons now on the dump and ready for reduction. This ore goes from $175 to $200 per ton, and will net $150. At this rate the clean-up will amount to $180,000. It is calculated that the run will take about three months. The lowest depth attained in any of the mines of the Christy Company is 200 ft, so that the ore is readily accessible; and if it turns out as expected, the company is to be congratulated on having acquired the property. They have about 50 men now on the pay-roll, and when the mill is enlarged, as Mr. Catlin proposes to enlarge it in the spring, this number will be considerably increased.

WILLOW CREEK DISTRICT.

A BRIGHT OUTLOOK.—*Silver State*, Nov. 14: A correspondent writes from Willow Creek as follows: The camp is just in that state of uncertainty common to new mining districts. The mill which is being erected by Harlan & McColley is fast nearing completion, and speaking from a moderate experience in such matters, I pronounce it an excellent mill in all its appurtenances. That large bodies of gold and silver-bearing ores exist in this district is beyond question, but the development of promising prospects peculiarly slow, though McColley & Harlan are working several claims with flattering prospects. The future of the camp is assured, and the question of time is all that remains to frighten the timid or weak-kneed. The mill company are entitled to great credit for their course and foresight in affording the opportunity for the development of this section.

ARIZONA.

PECK AND TURKEY CREEK.—Prescott *Courier*, Nov. 16; W. J. Chamberlain, connected with the Omaha and Pueblo reduction works and with the Denver sampling and refining works, visited Peck and Turkey Creek districts a couple of days ago. He found between 300 and 400 sacks of high grade Black Warrior ore ready to be shipped to Omaha for treatment .....As Mr. Chamberlain has purchased ores in almost every State and territory, he has, of course, a correct knowledge of the worth of this and adjacent mining sections as mineral bearing countries, and we were pleased to hear him make the assertion that Arizona is far better in this respect than New Mexico..... John Holmes, who has developed the Goodwin, Holmsite and other ledges in Turkey creek district, has now in dump, for sale, between 7 and 10 tons of high grade silver ore worth $6000 a ton. Mr. Chamberlain has made him an offer for the lot, agreeing to give him 90 per cent. of its assay value in advance of treatment.....Mr. John Howell is also here purchasing ores for the smelter he is about to build on Lynx creek.....Dennis May, of Martinez district, has a 250 ft. shaft on his Type mine. It is gold bearing. A specimen recently shown us a little larger than an English walnut, was fully ⅓ gold. It is, we have reason to believe, the richest mine in the western part of Yavapai county.

TONTO BASIN DISTRICT is fast establishing a reputation for itself. The section of country embraced in the district is east of the Verde river. Besides its mineral ores, it has abundance of timber near, with fine grazing facilities and some good farming land. When Mr. B. J. Wade was there a short time ago, Dr. W. W. Jones informed him that while this district was, as it were, in its infancy, development work satisfied him that it will very soon be one of Arizona's largest bullion producers. The Goodman, Excursion, and Golden Wonder mines are pretty well developed and carry sufficient gold to pay for mining, milling, etc. The Oxford, a silver bearing ledge recently found in the Mazatzal mountains, is said to be 43 ft. thick and well provided with silver. D. C. Morelaud, who discovered the Tiger mine, is now a resident of the Basin; he owns some good properties.....Dr. Belden who recently examined C. D. Reamis' property in Copper Basin, 12 miles from Pressott, express themselves pleased with the outlook. They represent the Basin as being a large copper field, the richest, they think, in the world.

THE DOSORIS, in Hassayampa district, the Silver Belt, the Belle, in Big Bug district, the Marcus, in Weaver district, are all yielding very rich ores, while the Tiger, in Bradshaw, has on the 300 ft. level a 9 or 10 ft. vein of ore which it is thought will pay to mill.....A glance through the newspapers of other counties of the territory satisfies us that mining is profitable in every one of them. The silver and copper mines of Cochise, Pima, Gila and Pinal counties are producing well. The mines of Mohave, Yuma and Maricopa are highly spoken of, so that look where one will, treasure is to be seen.

MINES AROUND WEAVER.—Arizona *Miner*, Nov. 17: In the early history of the settlement of northern Arizona, near Weaver, on the top of a high mountain, was discovered by a band of brave pioneers, the most marvelous placers, for their extent, ever found in any country. Upon about a half an acre of ground was secured over $1,000,000 in large sized nuggets. The country surrounding has plenty of gold in the earth, but owing to the scarcity of water and the character of the clay in which the fine particles of gold are imbedded, as yet no great headway has been made in making fortunes; however, it is and has been the opinion of mineralogists and scientific men that very rich ledges existed in and around Weaver. To a limited extent, developments have been made with very satisfactory results..... The Leviathan is a mammoth deposit which must sooner or later attract the attention of capital to its rescue from an almost dormant condition.....In close proximity to the Leviathan is the Marcus mine, owned by the Bates Bros. This ledge has received some development, and has surprised it owners by producing ore worth thousands of dollars per ton..... Adjacent to the Marcus is being opened the Van Arman, which, at a depth of 10 or 12 feet, has a vein of ore 5 feet wide, assaying over $300 to the ton.....Mr. Pattridge, who is the oldest settler at Antelope or Weaver, has some fine prospects; but owing to limited means has been unable to make proper developments. Aid will come to him some of these days and he will reap a deserved harvest for his many years' toil and perseverance.....Mr. Johnson has a very rich gold mine and well developed. He, with a partner, silently works away uncovering fine ore and showing plainly the size of his very rich mine. We hops to see some ons purchase this property and put up reduction works.....Weaver district has many fine ledges marvelous in richness. We venture the assertion that ere long Weaver will outdo Virginia City in its palmiest days.

IDAHO.

ATLANTA.—Correspondence Idaho *World*, Nov. 19: Now I'll give you what little information I have about the mines. The Monarch is the boss mine of Alturas, and is worked very systematically. Everything runs like clockwork. They have been taking out some of the richest ore this fall that I have ever seen in the country. The Last Chance is said to be a good mine. Their mill has been crushing good ore all fall. The company was working quite a force of men when I left, and taking out good ore. The Buffalo is too well known for me to mention. The Leonora mine was sold this fall. Capt. Baxter, superintendent, a well known mining man of Alturas, will put up a 20-stamp mill next season. The Monarch contemplates the erection of a mill, which will make 6 in Atlanta. There is one other mine that is working that I came near forgetting—that is the Tims. The ledge is small, but makes up in richness. The Julian Hill mine, when once developed, will be one of the best in Alturas.

MONTANA.

BAKER DISTRICT.—The indications are that the Magnolia mines are coming to the front as ore producers. Large capital has been interested in the district, and another season will probably rank Barker among the important mining regions of Montana.....The Bismarck *Tribune* says: "The First National Bank of Helena have in Maiden gulch, within 3 miles of Fort Maginnis, a 2-stamp oscillating mill, with A. M. Esslyr, a mining expert, as superintendent. His knowledge of ore permits him to guarantee the company he represents $50,000 for dividends at the expiration of a 3 month's run.....The Judith Gold and Silver Mining company have about 400 tons of ore on the dump, and ready for milling when their machinery arrives. Parties are now East purchasing machinery for this company. .....The Comet, Nevada, Florence, Helen, Golden Eagle and Silver Star companies are all taking out ore. .....The Consolidated Silver Mining company have interests in eight of the richest lodes now opened, and all of their ores assayed are found to run from $100 to $1,800 per ton. It is believed no interest will develop as richly as that of this company.....One-half interest in the Collar lead was lately sold to the Omaha Smelting works for $80,000, Geo. Mead, the purchaser, passing through Bismarck east Thursday last. This will be the nucleus to general transactions. No boom interests exist. Only ore in sight talks, and now the people who went into silver mining are jubilant over their daily discoverings.

NEW MEXICO.

BURRO MOUNTAINS.—*New Southwest*, Nov. 14: The Pittsburgh mine, an easterly extension of the Saint Louis is a paying property from grass roots down, and develop, increased value with increased depth. The ledge remains the same (pay streak over 5 ft,) carrying a sufficient number of fine pyrites to make the ore self-smelting, needing only flux or spar to thin the slag, which is hauled from one of the Queen City Copper company's claims near the smelter.....Col. P. R. Smith, the manager of the St. Louis, is making estimates of the cost and preparations to put in pumps of such capacity as will handle the water encountered in the bottom of shaft and lower levels. The sooner heavy pumps are put in place in this mine, the sooner will the problem of the extent of the ore body found below water level be known.

THE MARY MINE continues to improve as the work of exploration progresses. The face of the tunnel is strongly mineralized and looks decidedly encouraging for a body of ore.

THE FOUR FURNACES of the Valverde are in full swing, 3 of which are making copper matte while the other is roasting. The matte produced averages the same as ever. Forty-five thousand pounds of blister copper, 98 per cent. fine, was shipped to Baltimore this week. The old bottom of furnace No. 3 was taken out, resmelted and yielded nearly four tons of copper.

THE ORE at the smelter is accumulating very fast at the present time, as the furnaces are not of ample capacity to smelt all the ore produced by the different mines owned by this company.....Furnace No. 2. of the Queen City Copper company has been fired and is roasting, while furnace No. 1 is making matte. The laying of the pipe from the company's wells to the works is nearly complete. The water jacket will be started in a few days.

STARTED UP.—*New Southwest*, Nov. 14: The Shakespeare smelter has again started up, this time with excellent results. A car load of silver bullion was shipped this week and another is ready for shipment.....Work is being rapidly pushed on Johnny Bull mine in the San Simeon district. The main shaft is 35 ft. in depth, carrying at the bottom a 4 ft. vein of black oxide of copper, running from 40 to 50 per cent., and a ledge of mineral bearing rock about 13 ft. wide, outside of the rich ore, that contains yellow sulphurets that run between 10 and 20 per cent. in copper. About 400 feet from the shaft on top of the hill is an open cut 25 ft. wide and 14 ft. deep, in which no walls have been found, that contains rich gray and yellow sulphurets of copper of a high grade, Over 250 tons of pay ore are on the dumps of the mine. .....George J. Johnson, consulting engineer of the Arizona Copper company, the purchasers of the Longfellow and Metcalf mines at Clifton, A. T., has just returned from a visit to the mines in company with F. L. Underwood, President of the Merchant's National Bank, of Kansas City, this financial agent of the company. Arrangements have been made for a vigorous prosecution of work.

OREGON.

NOTES.—*Times*, Nov. 17: A favorable mining season is promised....The Josephine mine, owned by Wm. Bybee, will be put in running order by John Hall.....Many prospectors in southern Oregon and their number is constantly increasing.....W. H. Bonner & Co are putting the Centennial mine in Willow Springs precinct in shape for the winter's run.....Hays & Magruder are building another reservoir at their diggings on Rogue river and making extensive preparations.....Mills & Co., who own Birdseye & Strahl's claim on Birdseye creek, have fixed them up in good shape for the mining season. They are all experienced miners.....Capt. Kelly, of Coyote creek, who is in town this week, informs us that the miners of that section, like those of many others, have enough water to commence cleaning up ground left over last season.....John N. Hall, one of the commissioners of Josephine county, was in town last week. He showed us some exceedingly rich quartz taken from a ledge he recently discovered in Slate creek precinct, and which promises well.....Derickson & Co's quartz mill at Horsehead is at a standstill, on account of some disarrangement of the machinery. The party from whom it was purchased has arrived to straighten out matters. The company have good quartz in sight.

UTAH.

FRISCO.—Salt Lake *Tribune*, Nov. 17: Mr. J. M. Burke, who arrived yesterday from Frisco, says a large cave of ore was struck in the Cave mine within the past week. This ore is of excellent quality and is thought to be the largest body yet found in this great mine.....We learn that the Empire mine, Park City, is taking out some rich ore from 400-level, and that they are sinking 100 ft more. The owners of this property hope to make it a good paying mine with more development.

THE Ottowa correspondent of the Montreal *Gazette* asserts that a large number of artisans and others are coming into Canada from the United States, bringing their families with them, for the purpose of settling.

A large body of ore has been found in the Bullion of Paradise mine, Nev., and is the largest body yet found at any good depth in the district. This will encourage several other companies.

Oleomargarine and Butter Under the Microscope.

[Read before the San Francisco Microscopical Society by Edward J. Wickson, Secretary of the Society.]

The appearance of the imitation butter, commonly termed "oleomargarine," upon the San Francisco market makes it timely to call up the microscopical history of this compound, which is made by churning the softer fate of the slaughtered animal with sour milk, and adding thereto coloring matter and salt, producing an article which has a semblance to butter, but lacking the aroma and flavor of the choice product of the butter maker.

Soon after oleomargarine appeared at the East the question of tests to distinguish it from the genuine article arose. Both the chemist and microscopist attacked the problem, and both soon announced distinguishing reactions and appearances between the fat derived from the milk and that from the tallow. The chemists vary in their methods of distinguishing the false from the true, some relying upon detecting the absence of the finer butter fats which give the well-known aroma and flavor, others employing the specific gravity test, others making use of the different colors produced by the addition of proper reagents to the two articles in question. These tests are duly recorded in the chemical journals.

The microscopist rests his case upon the discovery in the oleomargarine of tracer of the crystalline fats found in the tallow, but not in the milk fats, the latter always existing in globular form, no matter in what condition the butter may be at the time of observation. The first announcement of this discovery in this country was made by John Michels, of New York, in a communication to the *American Dairyman*, dated June 1, 1878, in which he gave drawings of the microscopic appearance of oleomargarine and butter, which I have the pleasure of showing you this evening. Accompanying the drawings was this description:

I procured a small sample of oleomargarine, placed a fragment on a glass slide, covered it with a thin glass, and pressed it out to a thin film. A sample of butter was treated in the same manner. Both were then examined with a four-teuths objective and drawings made with the camera lucida. It will be noticed that the large, feathery crystals are characteristic of oleomargarine, and that the general appearance of the sample is different from that of butter, which merely shows the fat globules observed in milk, with here and there a crystal of common salt.

The announcement was met by contradictions by others who examined the materials microscopically in the interest of the oleomargarine makers, but that the appearances claimed by Mr. Michel do exist, I shall have the pleasure of showing you from a sample procured in this city.

The experts who examined oleomargarine in the interest of the makers were handled without gloves by other well-known microscopists, who examined the material in the public interest. It will not be worth while to go at length into the controversy, but rather to cite the announcements made by men whose authority as microscopiste needs no affirmation.

The *Scientific American* of June 15, 1878, contained the following:

Mr. Thomas Taylor, the microscopist of the Department of Agriculture, at Washington, has been examining under the microscope and comparing different specimens of butter obtained in the markets of that city, with the view of determining the difference between pure butter and that made from oleomargarine, or butter made by churning fat with cream. He finds that, when viewed under the microscope, pure dairy butter presents a uniform appearance as far as color is concerned. The forms seen consist of oil globules and the crystals of common salt. When viewed by polarized light very little change of color is observed; but when a specimen of oleomargarine is examined in the same manner, the field is speckled all over with shining particles, which change color with every quarter turn of the analyzer, and Mr. Taylor has demonstrated that these glistening points consist of crystallized fat. In using a power of about 250 diameters, animal tissue is also seen more or less over the whole field, and a thin sheet of the fat placed under a power of about 75 diameters exhibits the polarized light beautifully, each solid fat cell showing all the colors of the rainbow; and, on turning the analyzer or polarizer, the changing complementary colors are exhibited. The process of grinding the fat by means of rollers destroys the solid crystalline cell contents; but the glistening appearance remains the same under polarized light, only subdivided, as a natural consequence.

One specimen of the oleomargarine butter examined by Mr. Taylor was highly charged with animal tissue and the urate of magnesia, the crystals of which were well defined, showing that the fat used in this case was impure, and probably that of a diseased animal, which would seem to prove that the assertions made by the oleomargarine manufacturers as to the perfect purity of the fats used by them are not altogether correct.

From this it would appear that oleomargarine may be easily known from butter by the aid of the microscope, and that any impurities in the fats of which it is composed may be readily detected; and that it would pay large consumers of butter to microscopically examine their purchases so as to be certain of the quality or purity of the article they buy for butter.

With reference to the advice to consumers of butter to test their purchases by the microscope, I would remark that the observer must have some skill in manipulation, must secure a very thin film and use a moderately high power, or else he will fail to discover the distinguished characteristics of oleomargarine, and to this fact I think are due the statements of some who claim to have examined the materials, that the distinction pointed out could not be found.

To continue the review of authority on the microscopic examination of oleomargarine, I will present the results reported by Prof. J. Edwards Smith, of Cleveland, Ohio, as published in the *American Journal of Microscopy* for 1878:

I obtained three samples of oleomargarine from the manufacturers, and one sample of pure dairy butter from a farmer. The four samples were subjected to examination under the microscope; the objectives used were a ¼ inch of 100° by Tolles, and Spencer's late duplex, ⅛ of 180°. The oleomargarine samples were marked Nos. 1, 2 and 3. Nos. 1 and 2 were tolerable fair imitations of butter, No. 3 was a poor counterfeit. In samples 1 and 2 the microscope displayed the feathery crystals (margarine) described by Prof. Michels, although these were not constantly present in every field examined. By moving the slide, other fields were brought into view in which these crystals were much more prominent than those given in the cut accompanying Prof. Michels' paper. * * * Besides the crystals named, the samples gave "suspicious cells" in large numbers, accompanied by shreds and tissue fibers, many in a broken-down condition, while others appeared to be in a tolerably normal state, sufficient almost to establish the presence of voluntary muscle. * * * Sample No. 3 displayed fewer feathery crystals, but was the most suspicious specimen of the three. There were multitudes of suspicious cells, shreds and patches of tissue. * * * The sample of pure dairy butter gave fields just as represented by Prof. Michels, with the exception that crystals of salt were almost constantly present.

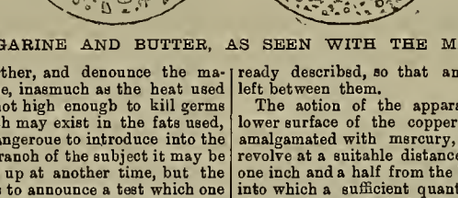
Another observer, Rev. Mr. Huber, describes in the *Southern Clinic* for 1880 the results of his examination of oleomargarine and butter, using Zentmeyer's grand stand and a Tollee quarter-inch objective. During the preceding two years he had examined several hundred samples of oleomargarine and butter. His results are described as follows:

The difference between natural and artificial butter under the microscope is a most marked one, as every one can see who will look at the two accompanying wood cuts. Oleomargarine shows over the whole field feathery and stellate crystals, which are never seen in genuine butter. I did not find one single sample of oleomararine free from them. While not every field of the same preparation showed as many as our illustration, and some few fields were nearly free from them, others showed a great many more, besides a number of suspicious looking things—shreds of tissue, muscular fiber, etc.—giving a rather irregular appearance to the whole, while the appearance of natural butter is very regular, showing of foreign substances only the cubical crystals of common salt. In oleomargarine the essential oil globules are of much less frequent occurrence than in butter, which consists almost entirely of them.

These feathery and stellate masses are margarine crystals. They are formed by the separation of solid fat from the natural fatty masses of the body in the cooling of the latter after death. Some very high authorities look upon these crystals as the incipient stage of decomposition, while their continual presence in oleomargarine, and their total absence in butter, show conclusively that there is an important difference between the two articles, and that the fat of natural butter is a different thing from that of oleomargarine.

I have treated the microscopic appearance of oleomargarine from the single point of distinguishing it from butter. The observere I have cited go much farther, and denounce the material as dangerous, inasmuch as the heat used in the process is not high enough to kill germs of organisms which may exist in the fats used, and which it is dangerous to introduce into the stomach. This branch of the subject it may be important to take up at another time, but the present purpose is to announce a test which one skilled with the microscops may easily apply, and thus free himself and his friends from the consumption of oleomargarine under the guise of dairy butter.

Oleomargarine. Butter.



OLEOMARGARINE AND BUTTER, AS SEEN WITH THE MICROSCOPE.

Amalgamating Gold and Silver.

So much attention is just now being directed to the question of the profitable extraction of gold and silver from their ores that the description of every new process brought forward is read with general interest. The invention of Mr. L. F. Gowane, of Cheapside, described in the *London Mining Journal*, relates more especially to machinery used for amalgamating, or extracting by means of metallic mercury, the particles of gold contained in auriferous quartz, stamped or otherwise pulverized, or of silver from silver ores similarly reduced to powder. It has for its objects novel methods of constructing and arranging machinery or apparatus by means of which the metal to be extracted is brought into intimate contact with the mercury, so that every particle during its passage through the machine is necessarily brought into such contact with the mercury, and great saving of the latter as well as of the gold or silver which is to be extracted is effected, as compared with machinery or apparatus for such purpose as heretofore ordinarily constructed and used, in which a considerable part of the metal, especially the very minute particles, passes away from the machine without being detained by the mercury, and either escapes and is lost or has to be recovered by subsequent processes. In order to put the invention in operation, he takes a vertical hollow shaft of sufficient hight, revolving in bearings formed upon or attached to a suitable framework or support of wood or other material, and having at its upper end a hopper into which the auriferous sand, powdered quartz or other material to be treated is admitted, together with a sufficient quantity of water. The auriferous sand and water may be allowed to pass into the hopper directly from stamps or other pulverizing machinery by which it has been reduced to powder, or it may be supplied gradually from any source by hand, or by elevators, endless screws, or other feeding mechanism of any of the ordinary well known kinds.

The vertical hollow shaft and hopper are set in revolution at the required speed, which may be varied according to the character of the material being treated, by steam, water, or other convenient power. He prefers to drive it by means of a horizontal shaft set in motion by such power and revolving in bearings formed upon or attached to the framing which carries the vertical hollow shaft, one end of such horizontal shaft being fitted with a beveled toothed wheel gearing into and driving a corresponding beveled toothed pinion upon the vertical hollow shaft, and its other end being fitted with a pulley by which it is set in revolution. The weight of the hollow vertical shaft, and of the appliances hereinafter described which are attached to its lower end, is supported by a collar arranged at any convenient part of its length, preferable at its upper end, such collar resting upon a fixed support or bearing in which it revolves, preferably with the intervention of a sufficient number of steel rings or washers.

At the lower end of the hollow vertical shaft is fixed a block, preferably of cast iron, having a vertical central opening at its upper part, which is fitted upon and attached to the shaft, the lower end of the opening communicating with a sufficient number (preferably four) of outlets curving downward and outward, through which the sand and water pass out into a circular horizontal pan or dish, preferably of wrought iron, which is supported upon a frame or foundation immediately below the hollow shaft. At the upper end of the hollow casting above described, where it is fitted upon the hollow shaft, is formed a collar, upon which is supported and fixed a horizontal muller or grinding plate, preferably of cast iron, which is made in four or more segments, bolted or keyed together, so that either of them can be readily removed or replaced when desired. The bottom of each of these segments is provided with a flat copper plate, rivetted or otherwise fixed to it. A circular inclined or vertical flange is preferably formed on the outer diameter of the segments, concentric with but of less diameter than the edge of the pan already described, so that an annular space is left between them.

The action of the apparatus is this: The lower surface of the copper plates, which are amalgamated with mercury, being adjusted to revolve at a suitable distance, preferably about one inch and a half from the bottom of the pan, into which a sufficient quantity of mercury is placed, the vertical shaft, together with the copper bottomed segments, are set in revolution, a supply of auriferous sand and water being admitted down the vertical hollow shaft from the hopper above. By the pressure of water the sand is pressed, not between the copper plated muller and the mercury in the pan, but absolutely through the mercury in the latter and on the copper plates, and in this way it is impossible for any particle of gold to escape amalgamation provided the ore be crushed sufficiently fine. The sand from which the gold has been thus extracted passes from under the muller and is carried with the water over the edge of the pan in which the latter revolves. The muller being in segments, either segment can be readily removed or replaced when necessary.

Where auriferous or argentiferous ores are to be treated, in which the metal is coated or combined with the mundic or substance which has no affinity for mercury, he uses the following process: The ore being crushed or reduced to the necessary degree of fineness, either dry or being thoroughly dried after such crushing, he passes it in a dried state through the machinery or apparatus already described to the mercury, in which has been added, in the proportion of about 1 oz. to 4,500 ozs. of mercury the following composition: He heats mercury to a temperature of about 300° Fahr., and to every 100 ozs. he adds 17 ozs. of metallic sodium, in small particles at a time, in order to avoid dangerous combustion, and he mixes alloy in the above-named proportions with the mercury in the pan of the apparatus.

The presence of the sodium in the mercury frees the particles of metals in the sand from their coating of mundic or other such substance as described, and insures their thorough amalgamation whilst passing under the muller. He does not confine himself to the precise proportions of the material named, which may be varied slightly to suit the varying circumstances. Where the sand is passed dry through the machine or apparatus as described, it is not necessary that the vertical hollow shaft should be of such hight as in the arrangement first described; and the hopper may be arranged immediately above the revolving hollow block to which the compound muller is attached, the sand being made to pass under the copper plates by the revolution of the latter, aided, if necessary, by revolving blades or screws, by which it is forced down. The pan may in some cases be surrounded by a casing or jacket, steam or hot water being admitted into the space between, so that the mercury may be heated and kept at any desired temperature. The bottom of the muller may be provided with ribs or projections, or depressions, straight or curved, in order that every particle of the sand may more certainly be brought into contact with the mercury.

A New Blasting Explosive.

Nobel's Gelatine.

On Tuesday, says the *Colliery Guardian*, a series of most interesting experiments or tests took place at Warmsworth, about four miles from Doncaster, for the purpose of exhibiting the extraordinary power of the new explosive known as blasting gelatine, patented by Mr. Nobel. From what it did, it appears to be the most powerful explosive yet introduced, and promises to supersede most others, seeing that its disruptive force is 50% greater than that of dynamite, being by no means dangerous, for it can only go off when the detonator is attached to it. The gelatine in appearance is of a light brown color, and has the advantage of exploding when the hole is filled either with water, clay or gravel. Probably there is no better place for testing the qualities of the explosive than Warmsworth Cliff, where the limestone rises from the surface to a hight of upwards of 100 ft., presenting a bold and massive appearance, extending laterally for a considerable distance, in one direction not less than a mile. At the principal cliff where the limestone appears to be very pure, lying in alternate layers or beds, without any intervening covering, the first experiments were made. In holes about two feet in depth and less than one inch in diameter, a couple of cartridges, each weighing ½ ounces, were inserted and then exploded by means of an ordinary fuse. Soon there was a series of reports that could be heard for a long way, shaking the ground around, but not sending the riven stone any distance. On going to the place where the shots had been discharged, there was a large quantity of fallen stone, whilst the face of the mass was split for a distance of something like 20 ft. from the floor upwards, so that there would be a large fall by loosening some of the cracked strata. On going to another part of the cliffs a short distance off, several shots were discharged, the workmen taking a great deal of interest in the proceedings, and accustomed as they were to the use of dynamite, powder, and indeed most known explosives, they expressed their surprise at the power of the gelatine, and the vast amount of work done with so little of it. But its value was more fully shown when a solid block of hard stone, weighing about two and one-half tons, was shivered into pieces with a single cartridge of less than 2d. value. Another stone, weighing about 30 tons, was also acted upon with a few cartridges, and the result was that a large proportion of it was broken up. A short walk after this brought the party to another of the cliffs belonging to Messrs. Lockwood, Blagden and Crawshaw, and several trials were made where the work was most difficult, and where powder and other explosives had not been of much use. There was no difficulty as regards working at the face, but lifting up the floor, it was stated by the workmen, was no easy matter. The gelatine was here applied to the surface, and two shots split up a large quantity of the stone, which appeared to be highly gratifying to the men in particular, who evidently appreciated the new explosive as calculated to lighten their labors and lessen the danger they have hitherto been exposed to in the use of dynamite and powder. Other experiments were carried out, and a considerable portion of the limestone was broken up with the greatest ease, and with a comparatively trifling expenditure of the explosive. Messrs. Blagden and Crawshaw, who were present at the different places where gelatine was used, expressed themselves as much pleased and highly satisfied with the work done, and the superiority of the new explosive over all others that had hitherto been used. The experiments, it may be said, were conducted by Mr. Robert Lonie, who was assisted by Mr. Bramley, of Wombwell, and the whole of the proceedings were watched with a great deal of interest, and it was a marked feature that the gelatine involved no danger where only ordinary precautions were taken.

FINE DUST TUNNELS.—The Albion mine, at Eureka, is running three tunnels 100 feet into the hill back of the hoisting works for flues through which the smoke from the smeltere will pass. This will enable the company to save pretty much all that is in the ore, the flue dust being worth some $40 per ton.

IRON THAT RESISTS ACIDS.—A German patent has just been taken out for the manufacture of bottles, etc., from cast iron, containing 12% of silicum, a compound which is said to resist the action of the strongest acids. It is also recommended for the iron plates of zinc and iron galvanic batteries.

The Engineer.

The Manchester, England, Ship Canal.

This project appears to he in a fair way toward a practical issne. A definite plan has heen adopted, and a committee has heen authorized to raise funds to obtain the necessary parliamentary powers for carrying out the undertaking. The scheme adopted is, however, not the one which has been so long before the public of Manchester. The original scheme was to deepen and widen the Irwell and Mersey rivers so as to allow sea-going steamers at all times to reach Manchester. According to the present plan, however, a ship canal is favored in preference to tidal navigation, and it is proposed to continue the tidal river only to a certain point, and to construct from that point to Manchester (a distance of 15 miles) a ship canal with locks to raise the water to near its present hight at the proposed site of the docks at Manchester. The estimated cost of the undertaking is $27,000,000. The project may thus be considered to have at length assumed a tangible form, but there now remains to be overcome a number of difficulties which are of a sufficiently threatening character to command more than passing attention. Both the interests of Liverpool and those of the railway companies are involved in the undertaking, and it is but natural that an active opposition to its execution should be created. Rumor has it that even now there are muttered threatenings of retaliation, one form of which is that Liverpool should itself commence cotton manufacturing as a set-off against the injury that city might possibly receive should the canal project be carried to a successful termination. With all these difficulties, no doubt, the promoters have fully prepared themselves to contend, and should the construction of the proposed canal he capable of practicable realization, the business interests of Manchester will not fail to secure the enormous benefits which would he conferred upon the local trade.

An Underground Railway System for Paris.—An extensive scheme for an underground railway system for Paris has been presented hy MM. Sihen and Soalie, and has met with such favor that it will most likely he undertaken at an early day. The promoters propose to form a central line from Saint Cloud to the Lyons terminus, from which would branch a large outer circle and a smaller inner circle, with additional branch lines to the various termini. The stations are very numerous and close to each other; most of the waiting rooms are to be overground, whence commodious stairs are to lead to the platforms. A central station is to he erected at the Palace de la Bourse. The length of the railway, with all its branches, is to he nearly 24 miles. The cost of construction is estimated at $30,000,000, or $1,250,000 per mile. The fares are to he, for any distance, 10 cents for first-class, and four cents for second-class. Two cent tickets are to he issued to workmen.

A Rocky Mountain Railway Tunnel.—The Denver and South Park division of the Union Pacific railroad pierces the main range of the Rocky mountains, 150 miles southwest of Denver, Colorado. The length of the tunnel is 1,700 feet, and its altitude above the sea 11,500 feet. The approaches on either side are described as marvels of engineering skill, laid through scenery unrivaled for grandeur and magnificence. Although the tunnel commences with a sharp curve at its eastern end, so nicely was the engineering done that when workmen from either side met in the heart of the great snowy range, they found only about one inch variation in the respective lines. This tunnel, said to he the highest in America or Europe, leads to the new silver region of Gunnison.

The Brooklyn Bridge.—The telegraph companies are utilizing the Brooklyn bridge at a rapid rate before it is finished. The Secretary of the company says there are no fewer than 350 wires already in position on that structure, many of which are private commercial telephonic wires. Many of them are gathered in a single insulated cable, as in the case of the Metropolitan Telephone Company and the Gold and Stock Telegraph. Some of the cables contain over 30 wires. The Bridge Company receives no inconsiderable revenue from these telegraphic wires, each one of 350 paying $30 per annum. It is a condition that none of these wires shall interfere with the work on the bridge.

A New Telegraph Company.—A. T. Beard, of Boston, is about to embark in a company soon to be organized to build and operate a telegraph line between New York and Chicago; the wires to be steel with copper covering, and one-fourth of an inch in diameter.

Seventy-six courses of stone, making 152 vertical feet, have been laid since work recommenced in earnest upon the Washington monument. Its height is now 302 ft.

The largest and oldest chain bridge in the world is said to be that of Kingtung, in China, where it forms a perfect road from the top of one mountain to another.

Roman Aqueducts.—At the zenith of her grandeur, Rome had 11 aqueducts, whose aggregate discharge was equivalent to a stream 20 ft. wide hy 6 ft. deep.

Useful Information.

How a Snake Gets a New Suit.—"Some people think that snakes only shed their skins at certain seasons of the year," said the keeper. "That's a mistake. If they are well fed and kept right warm they change their coats about every eight weeks through the year." "Does it pain them?" "Not a bit of it. You see, the skin of a snake does not increase in size as a reptile grows, as with us. While the old skin is getting smaller by degrees a new one is forming underneath, and the other gradually gets dry. When it is ready to shed it loosens around the lips, and the reptile rubs itself against the earth or the rock in the cage, and turns the upper part over the eye and the lower part over the throat. Then it commences to glide around the glass case, all the time rubbing itself against something until the entire skin is worked off. Sometimes this takes three days; occasionally they get rid of the incumbrance in a few hours. I don't believe they have a bit of intelligence. For all I feed them and care for them, they would as lief bite me as any stranger. I can handle a good many of them safely, but it's only the knack of the thing—not that they won't bite, but that they can't get the chance."

The Best Wood for Fuel.—In the bulletin of the United States Census Bureau, recently issued, giving the relative merits and value of 50 varieties of wood as fuel, some very interesting information is found. The results presented in the bulletin were arrived at, it is stated, by the most carefully conducted experiments, the calculations being made from dried specimens dressed to a uniform size. Mountain mahogany heads the list, and it is noteworthy that this is the only tree growing in the United States the specific gravity of which is greater than that of water. Second in fuel value is the Southern pine, a very light wood, having only a little more than half the weight of mountain mahogany. Hickory is third on the list. Cedar ranks before white oak, and white elm outranks sugar maple. The secret of the remarkably high rank of the Southern pine is the large amount of hydrogen it contains.

Elevated Railroads are Amenable for Damages to Property.—Five years ago Rufus Story, of New York city, sued to restrain the New York Elevated Railroad Company from constructing and operating its road through Front street opposite his premises. The action was tried in the Court of Common Pleas in October, 1877, and resulted in a judgment for the railroad. The case was carried to the Court of Appeals, and the final arguments were made last June in Saratoga, John E. Parsons and William M. Evarts appearing for Mr. Story, and David Dudley Field for the railway company. The Court of Appeals rendered its decision October 17th, reversing the decision of the lower Court, and practically declaring that the owners of property along the lines of the elevated roads have a right to recover damages where their property has been injured in value by the construction and operation of such roads.

Wall paper should not, in the opinion of Dr. Baker, who read a paper on the subject at the recent gathering of scientists at Montreal, he manufactured in a manner to he air tight. He says that, hygienically considered, the walls of a house should he porous like our clothing, having free intercourse with the open air. He thinks that waterproof paper causes increased dampness of the walls, as the stoppage of circulation of air prevents their drying. This prolonged dampness of the walls he considers unhealthy and productive of other evils. Dr. Baker advocates the old fashioned whitewash walls, instead of wall paper or their substitutes.

To Clean Kid Gloves.—Mix dry potter's clay into a thin paste, with "deodorized" benzine; mount the glove on suitable dummy forms, and go over every part with this paste. Then plunge the gloves into a quantity of pure benzine for half an hour; press out excess of liquid, dry in the air, and then rub into every part as much of a mixture of equal parts of the yolk of eggs and flour as the material will absorb. For white leather substitute half glycerine and white of egg for the yolk.

Improved Mortar.—Sawdust is said by some one to he better than hair in protecting rough-cast from peeling and scaling under the influence of frost and weather. The sawdust should he first dried, and then thoroughly sifted, in order to remove the coarser particles. A mixture is then made of two parts sawdust, five parts sharp sand and one part cement, which should be thoroughly stirred together and then incorporated with two parts of lime.

Light and Dark Gold.—To produce light and dark shades of gold leaf the metal is alloyed with silver and copper. The addition of the baser metals lessens the malleability, and as the leaf is sold hy superficial measure, and not by weight, adulteration is kept at the minimum.

Value of the Bell Telephone Patent.—The Bell patent would, it is considered hy those competent to form an opinion, he cheap at $10,000,000. The consolidated telephone interests of the United States are estimated at from $100,000,000 to $150,000,000.

Canning Grain.—A new method of storing grain is proposed, in air tight bins or cylinders of sheet iron, to be sealed after a partial exhaustion of the air. It is said that wheat, flour and bread so stored for seven months have been found in excellent condition (as might have been expected), and that taking into account the security of the grain against dampness, fermentation, attacks of insects and large vermin, fire and other risks, when sealed up in a partial vacuum the new plan is more economical than ordinary storage in a granary.

Glass Napkins.—Spun-glass napkins are a recent addition to the supplies of luxuries, which people who indulge a taste for oddities will probably not consider too high-priced at $100 a doz n. One on exhibition in St. Louis is pearl shade, the size of an ordinary breakfast napkin, and almost as pliable as silk. The felling consists of minute glass threads, crossed by a silk chain, and the fringe of glass fiber is about two inches long.

Drying the Hair.—Ladies dislike to wash their hair because it is so difficult to dry it, but there is need of its being cleansed with water at least once or twice a week. The best way to dry hair is with a soft, thick linen towel. Throw this over the head and rub the hair briskly for some time. If dried hy the fire its vitality is injured, but the aid of the sun may he called in, after rubbing with the towel till most of the water is absorbed.

Wood for Small Things.—A Maine paper states that poplar, spruce, elm, and all good fiber woods are now assuming much importance from the uses to which they may be put in manufactures. The increasing demand for thread, spools, excelsior, clothes pins, and many other wood manufactures, gives increasing interest to our forests.

Good Health.

How We Digest.

To make the process of digestion simple, let me say that it begins in the mouth and ends in the lungs. A man swallows a mouthful of bread. We follow it from his mouth down through the œsophagus to his stomach. It now, hy a peculiar motion of the stomach, is moved about in the stomach, and as it touches here and there, gastric juice starts out, like sweat upon the forehead, and wets the bread. After a couple of hours of revolving about within the stomach the bread is changed into something that looks like buttermilk. This is chyme. Now the gate at the right end of the stomach opens and lets this chyme pass through the first parts of the intestines. There two liquids are poured in, one from the liver—the bile—the other from the pancreas—the pancreatic juice. These induce certain changes in the liquid bread which makes it resemble milk. Now it is known as chyle. Innumerable little mouths which open within the intestine suck up the milk, or chyle, carrying it to a small canal, the thoracic duct, which lies upon the backbone, and through this it runs up to the upper part of the chest and is poured into a large vein just under the left collar-bone. Through this vein it reaches the right side of the heart, and is then forced into the lungs, when it comes in contact with the air. Now a wonderful change comes over it. This is produced hy the addition of oxygen to the milk-like fluid. For a given quantity of this chyle a still larger quantity of oxygen is added, and the compound which comes of this union between the bread and the oxygen is the nutriment which supplies the wants of the system. What takes place in the lungs is more important than anything that precedes it in the process of digestion. For example, a man may live on fried salt pork, hot saleratus biscuit and strong green tea (I don't know a worse dose); if he lives on the Western plains and breathes pure air he will have a purer blood, healthier skin, and will be freer from humors than another man who lives upon the choicest grains and fruits, but who, constantly breathes the air of a close, furnace heated house. In other words, we may truly say that, in considering the great function of digestion, the lungs really play a more important part than the stomach itself. It is really vital that the first and last step in digestion should be well done. First, chew well, and last, breathe well. If those two duties are well performed, a substantial contribution will he made to our welfare.—*Dr. Dio Lewis.*

Moonstruck—Effects of the Moon.

Some one has written upon the effects of the direct rays of a full moon upon the human system and upon vegetation:

"The sun shall not smite thee hy day nor the moon hy night." This beautiful verse expresses the belief, common in ancient days, that the moon exercises a baleful influence upon those exposed to her direct rays. In modern times the pernicious influence of the moon has been doubted, and even denied; but whatever the influence of the moon in the temperate zones, within the tropics it is very injurious to sleep exposed to its rays, especially when at the full. On a voyage to the antipodes, when near the line, a Maltese sailor, who was a most comical fellow, slept for some hours on the boom with his face toward the full moon. On awakening in the morning the muscles of the right side of his face were contracted so that every attempt to speak was attended with the most ludicrous contortions. Feeling sure that something was seriously wrong, the doctor gave him some medicine, the muscles gradually relaxed, and in the course of a week he was well again.

Some five or six years ago, when sailing from Tahiti to Mangia, a little boy of mine, in perfect health, was thoughtlessly placed hy his nurse in his berth, the slanting beams of the moon falling on his face. Next morning he was feverish and ill, and it was two or three days before he was himself again. On the Island of Aitutaki, a native woman was watching night after night for the return of her husband. While doing so one night she fell asleep, the moon's rays pouring upon her face. On awaking she felt ill, and her eyes were drawn on one side. Considerable interest was felt hy the islanders in her case. Eventually, however, her eyes were restored. These facts illustrate the injury done to human beings hy the moon in the tropics. Yet I never heard of insanity or death resulting from this cause.

It is well known, however, in tropical countries, that the moon's rays occasion the rapid decomposition of flesh and fish. A number of bonitas having been caught one evening near the line hy a friend of mine, the spoil was hung in the rigging of the ship, and was thus exposed to the moon through the night. Next morning it was cooked for breakfast. Symptoms of poisoning were soon exhibited hy all who partook of it—their heads swelling to a great size, etc. Emetics were promptly administered, and happily no ones died. The natives of the South Pacific are careful never to expose fish—a constant article of diet in many islands—to the moon's rays hy any chance. They often sleep hy the seashore after fishing, but never with the face uncovered. The aboriginals of Australia do the same. A fire answers the same purpose.

Habits of the Hair.

A prematurely bald physician in Thirty-fifth street was asked a number of questions about the growth and habits of the hair.

"In the first place," he said, "do you know what hair is, anyway?"

"Only in a general way, perhaps."

"Then let me tell you in a word. It is an elongated epidermic appendage. Its essential structure consists of an assemblage of epidermic cells, at the bottom of a flask, shaped follicle, in the substance of the skin, supplied with blood hy vessels distributed to its walls."

"Can hair he made to grow on a bald head?"

"Not as a rule. In debilitated persons the hairs sometimes fall out spontaneously, or with slight assistance, and if the bulb alone comes away, and the sheath and germ remain behind, they are capable of reproducing the hair, under proper treatment or favorable circumstances. The short and pointed hairs on the scalp of old people show that new shafts are constantly forming. The nutrition of hair is affected through vessels which are in contact with their tissue, without entering into their structure, so that causes affecting the general health, or affecting the health of the skin, also affect the nutrition of the hair."

"What causes premature baldness?"

"In a great measure the violation of hygienic rules, and the excess of mental and physical labor in a climate foreign to the race."

"Is there a greater disposition to gray-headedness in this country than in others?"

"Well, some well informed people think that it is about the same in all civilized countries; but, if there is any difference, it is because of the hurried and unhealthful habits of life and mental exercise among Americans."

"What is the chemical action which produces gray hair?"

"Accurately speaking, that's one of those things that no fellow can find out. The color of the hair depends partly on the presence of pigment granules, and partly on the existence of air spaces, which cause it to appear dark hy transmitted light. In Albinos and gray-haired people this coloring matter is simply absent."

"Is it the case that hair may, from extreme fright or other strong emotions, turn white, as it is said, in a single night?"

"It is an undoubted fact. Just how the change takes place is a matter of conjecture. But it may perhaps he explained hy some chemical action upon the oily coloring matter. This oily matter would he withdrawn from the hair under conditions of cold, debility, or insufficient food."

"Does gray hair then become dead?"

"Not hy any means. The loss of vitality does not necessarily follow the loss of color, for gray hair often grows vigorously. For that matter hair will grow after the body's death. One of the causes of premature baldness and grayness is tightly fitting and unyielding hats."

"Are any of the thousand and one preparations for restoring the hair of any value?"

"Tonics and stimulating applications are sometimes beneficial. When the hair is thin and falls out easily shaving the scalp will often produce a thicker, firmer and darker growth.—*N. Y. Sun.*

TABLE OF CONTENTS.

EDITORIALS—Lead Smelting in the Ore Hearth; Useful Household Device; Blake's Paper File, 337. Passing Events; The Mint Director's Report; Southwestern Nevada; Academy of Sciences; Production of Gold, 344. Working Auriferous Silver Ores; The Divining Rod as a Mining Implement; New Hurdy-Gurdy Wheel, 345. Patents and Inventions; Notices of Recent Patents; Railroad Travel in This Country and in Europe, 348.

ILLUSTRATIONS.—Elevation of the Ore Hearth, Partly in Section; A Useful Household Device; Blake's Bill Post, 337. Oleomargarine and Butter, as Seen with the Microscope, 342. New Hurdy-Gurdy Wheel, 345.

CORRESPONDENCE.—Park City Mining Notes, 338. Notes from Eureka, Nevada, 348

MECHANICAL PROGRESS.—The Rolling of Steel Ingots with Their Own Initial Heat by Means of the "Soaking Pit" Process; Plain Facts About Boiler Explosions; Why Wood Joists are Safer than Iron in Case of Fire; Size of Pulleys, 339.

SCIENTIFIC PROGRESS.—Velocity of Falling Water; Sound; Progress in Geological Science; Determining the Color of Water; Some Phenomena Presented by Metals; Phosphorous in Charcoal; The Future of Niagara Falls; Formation of Alloys by Pressure; Hydrogen Gas in Steam Boilers; The National Geological Survey; The Telephone in the Fifteenth Century, 339.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 346.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Utah, 340-41.

THE ENGINEER.—The Manchester, England, Ship Canal; An Underground Railway System for Paris; A Rocky Mountain Railway Tunnel; The Brooklyn Bridge; A New Telegraph Company, 343.

USEFUL INFORMATION.—How a Snake Gets a New Suit; The Best Wood for Fuel; Elevated Railroads are Amenable for Damages to Property; To Clean Kid Gloves; Improved Mortar; Light and Dark Gold; Value of the Bell Telephone Patent; Canning Grain; Glass Napkins; Drying the Hair; Wood for Small Things, 343.

GOOD HEALTH.—How We Digest; Moonstruck—Effects of the Moon; Habits of the Hair, 343.

MISCELLANEOUS.—Amalgamation; The Denver Exposition—No. 14; New Reduction Works in New Mexico; Prospects in Atlanta, Idaho, 338. Oleomargarine and Butter Under the Microscope; Amalgamating Gold and Silver; A New Blasting Explosive, 342.

NEWS IN BRIEF—On page 348 and other pages.

Business Announcements.

Patents—Geo. B. Davis, S. F.
Books—National Book Co., New York.
Partner Wanted in Silver Mine.

Passing Events.

The local papers still come to us with more or less election talk, and to a certain extent local mining news is neglected. There are no startling events connected with the mining interests just now. The winter days are not favorable for prospecting in most regions, but wherever it can be prosecuted work is going on.

The stoppage of work at the Cherokee and Gold Stripe mines, in Plumas county, works hardship to that locality; especially, as it is said there is no need for such action, and it is thought to be a "freeze-out operation." All the private mines in this region are reported doing well.

Among the recent noticeable transactions in mining operations is the sale of the Drum Lumon, a big Montana mine, for $15,000,000, to a London syndicate. The ore vein of the Drum Lumon is 80 ft. in width, by actual measurement, all pay ore. The ore surrounded and in sight is over 250,000 tons. With large and improved machinery, including all modern appliances, the yield from the mine will be immense. For the erection of mills, etc., the London syndicate is to have a working capital of $500,000.

The trial between the Copper King and Copper Prince, Bisbee, Arizona, will shortly be in progress, and will attract great attention. Experts are already on the ground.

The Mint Director's Report.

The annual report of Horatio C. Burchard, Director of the Mint, has been issued from the Government printing office, Washington. The report is for 1881.

To procure the information necessary for preparing and making this report, besides obtaining from depositors in the usual manner the locality of production of the gold and silver brought to the mints and assay offices, the assayers and superintendents in charge of institutions in the mining regions were directed to make special inquiries and endeavor to ascertain the yield of the mines and the amount of bullion handled by dealers, bankers and transportation companies and treated at smelting and refining works in their respective localities. Information was also gathered for the same purpose by personal visits to the most important mining fields, and by correspondence and special reports from gentlemen concerned in or familiar with mining operations, and by the collection and tabulation in the Mint Director's office of such published statements and statistical material as seemed suitable and reliable.

From these sources the Director presents not only a summary of the yield of the mines of the United States for the year, but also detailed statements or estimates, approximately and sufficiently accurate, giving the product of the principal States and Territories, and often in many cases of the counties and districts.

The opening chapter of the work is devoted to the question of bullion product. Then there is a chapter to each State and Territory, giving more or less details about the mines. There is a very complete chapter on General Statistics, containing numerous carefully arranged tables showing product, coinage, exports and imports. There is also a chapter on Statistics of Production of Foreign Countries.

Under the heading "Miscellaneous" the following subjects are treated: "Mining Machinery," by Charles G. Yale; "Quartz Crushing Machinery," John Richards; "Milling of Gold Quartz," Melville Attwood; "Gold from Sulphurets," Mellville Attwood; "Auriferous Gravels of California," John Hays Hammond; "Cause of Rustiness and of Some of the Losses in Working Gold," T. Eggleston. All these chapters, except the last, are by San Francisco writers. There is an index of mines appended to the book, an index of localities, and a general index of subjects. Aside from those mentioned, the bulk of the work has evidently been done by Mr. A. M. Lawver, of the U. S. Branch Mint in this city, F. P. Grose and Frederick Eckeldt, of the Mint Directors' office. California, Oregon and Nevada were treated by Mr. Lawver, who has showed real industry, and has really compiled a great deal of useful information.

In view of the limited appropriation for such a purpose, and the fact that only statisticians, and not mining engineers, are regularly employed for the work, the report of the Director is quite creditable.

We notice a disposition among some of the technical papers to belittle this report, which is unjust. The information is obtained in the same way and often the same method as it was formerly by the U. S. Mining Commissioner, and the general result is about the same. In fact, the title might be "Mineral Resources West of the Rocky Mountains," as well as "Production of Gold and Silver in the United States." It is patterned after the Mining Commissioner's Report exactly. For his several articles the Commissioner was dependent on writers outside, and he had no regular staff except a couple of deputies. Experience gave these gentlemen opportunity to collect information more readily, perhaps, than it is collected now. Taken altogether, however, the report will compare very favorably with those produced by the Mining Commissioner.

The fact of the matter is, the collection of mining statistics is something entirely out of the Mint Director's proper duties. The care of such matters should be in the hands of persons specially fitted by profession to undertake them. Nevertheless, the Director has acquitted himself creditably in his task, and gives us a report of value for reference. It represents a large amount of work, and will give a very good idea of the range of our mining interests. The compilation shows some crudities, and evidences are apparent of a good deal of "office work;" that is, part of the compilation has evidently been made by persons unfamiliar with the localities of the mines. More careful editing by some one familiar with mining would have given a more condensed and improved report, as some of the statements are not wisely considered.

To expect such a report to be technically accurate, however, or to expect the Director to give his personal attention to every detail, is too much. He simply gives a resume of work in a general way, showing us the details of production and such statistics as will show the comparative yield of localities. We can expect no more. The report occupies nearly 800 pages, and, as far as we can see, covers its ground very well. It is, of course, not perfect, but will compare favorably with any of like character before published; and, having read them all, and having contributed more or less to nearly all, the writer is in a position to judge.

Southwestern Nevada.

We shall shortly publish an edition of the MINING AND SCIENTIFIC PRESS devoted to the interests of southwestern Nevada. This extensive region is now coming rapidly into prominence from its various mining districts which are now being rapidly developed. The Carson and Colorado railroad runs down through the center of the region, and it is largely to its influence that the development of the country is so rapid. Means of transportion for machinery and ore are now at hand, and the miners can with confidence call the attention of capitalists to their claims. We have sent a special correspondent over the road and to the different mining camps, and as soon as we have prepared all the material will issue the extra edition. A new and comprehensive map, showing the main mining districts and routes, will be given.

The region referred to is attracting a good deal of attention and deservedly, according to the following item from the Virginia *Enterprise:* "There is considerable travel on the Carson & Colorado railroad just now. Much of this is due to the attention which the mines along the road are attracting. At Mount Cory and Mount Grant a number of men are at work, and will be kept busy all winter getting out ore from the different mines. In the spring a genuine boom is expected in this part of the country. The Downeyville mines are showing up new developments every week. The ore is immensely rich and mostly silver. In Garfield district prospectors are still actively at work. Several of the claim-owners have been offered good prices for their properties, but they do not appear to be on the sell. At Candelaria the Northern Belle mine is producing ore of extra quality. The new strike made by Superintendent Bobby Jones just before his death is widening out and the ore is of higher grade than any taken from this mine for a long time. Superintendent Price, who now has charge of the mine, has a good force of men employed, and is working the ledge for all it is worth. Considerable is also being done in some of the other mines.

Academy of Sciences.

The regular meeting of the Academy was held on Monday evening, Dr. Behrin the chair. J. G. Lemmon presented a live rattlesnake of a new variety, caught by him and his wife in Arizona among the mountains along the border of Mexico. Captain Robert W. Simpson presented an enormously large burrowing clam or rock oyster, from Puget Sound, known as the *Zirphea Crispata*, an edible variety. Many valuable minerals were presented, among which was a full assortment of nitrate specimens from Peru; also a large block of Oregon nickel. Hitherto this variety has never been found in large quantities, except at Noumea, in New Caledonia. The mineral is found on Piney mountain, 2,500 ft. above the level of Cow Creek valley, Oregon, and appears as croppings. It is very easily worked, while other nickel ores found in the United States are sulphurets and expensive to work.

Robert E. C. Stearns, Ph. D., then read a paper on the "Family of Fresh Water Mussels, and their testimony regarding the geological age of the recent fossil footprints discovered in the State prison yard at Carson, Nevada." This paper showed great research and careful study. The author analyzed and described the *Anodons* and *Physa* varieties found in the sandstone strata overlying the Carson footprints, where they exist above the fossil tracks of the mammoth, buffalo, horse, wolf, sloth, heron and perhaps man. These shells are everywhere distributed from mountain ranges toward the sea.

Dr. H. W. Harkness, M. D., read a list of 40 new species of fungi which he had gathered and found to be attacking the foliage of our trees. Some which he described are now found in America for the first time. One is a cause of the sickness common among sycamore or button wood trees, striking its first growth of leaves as a blight, nearly all of which it kills. Sycamore trees at the East have long suffered in a similar manner. He spoke more fully of a fungus now doing much mischief among the pine trees of both the Coast Range and Sierra Nevada. Its ravages are very marked on the pine groves at Monterey, California. They cause from 15 to 20 large swellings on the trunk and limbs of full grown trees, which exhaust their vitality. It is now busy arresting the growth and proper development of tens of thousands of valuable trees in the Sierras. Even some pine foliage in our Golden Gate Park is already slightly affected.

A CLOSE MARGIN.—The Mexican mill keeps 200 people employed directly and indirectly, says the *Carson Appeal*, all on a margin of 50 cents per ton for every ton of ore crushed. A large amount of capital is invested in the enterprise and hundreds of months fed daily, yet the investors only realize half a dollar per ton on ore which costs over $9 to handle. In this instance capital is neither cruel nor grasping, when the additional facts are taken into consideration that at any time the grade of the rock is liable to fall below the 50¢ margin and leave the loss to the company.

Production of Gold.

California does not produce as much gold as it formerly did, although it still yields over $18,000,000 of it every year. And this keeps California abead as the principal gold-producing region of the world. In our country Dakota, Colorado and Montana follow, in the order named. Of the gold production about $26,000,000—nearly four-fifths of the whole product of last year—came from the mines of the Pacific coast, including Nevada, Idaho and Arizona, and was deposited at the San Francisco and Carson mints, while nearly $8,000,000 were received at Philadelphia and New York from Colorado, Dakota and Montana. The domestic production of gold in 1881 was $34,700,000, which shows a decline of over one and a quarter millions from the Mint Director's estimate of the previous year. The yield of gold in the U. S. in 1881, according to this official estimate, was as follows:

	Gold.
Alaska	$ 15 000
Arizona	1,060,000
California	18,200,000
Colorado	3 300,000
Dakota	4,000,000
Georgia	125,000
Idaho	1,700,000
Maine	.....
Montana	2 330 000
Nevada	2,250,000
New Mexico	185,000
North Carolina	115,000
Oregon	1,100 000
South Carolina	35 000
Tennessee	5 000
Utah	145,000
Virginia	10 000
Washington	120 000
Wyoming	5 000
Total	$34,700,000

The amount of domestic gold used in the arts and undeposited at the mints must, in part, be estimated. The Mint Director thinks it may safely be placed at half a million dollars; for while the manufacturers' statements received at the Mint Bureau show that fine gold bars to the value of $6,230,000 were used by them in manufacturing in 1881, the aggregate value of the fine gold bars issued for manufacturing purposes by the New York Assay Office and of all the fine gold bars made at the mints during the same period was only $5,960,094 31. The remaining $270,000 of the fine gold bars reported by manufacturers must have been obtained from private refineries and assayers, by whom fine gold bars are also prepared for use in manufactures, consisting principally of domestic bullion received directly from mines or smelting works. The statements of the manufacturers did not include the value of the native gold in the form of grains, ingots, lumps, etc., used for ornamentation and in the arts, which would amount to a considerable sum.

Although this estimation is based upon statements and reports made by the mint authorities for the fiscal year ending in June, 1881, the facts they disclose show that to ascertain the total gold production during the calendar year an addition to the domestic gold bullion deposited and exported of perhaps half a million of dollars should be made for bars made at private establishments and for native gold used in the arts. From those data the yield of gold from the mines of the U. S. in 1881 placed by the Director of the Mint in round numbers at $35,000 000

This is over $4,000,000 higher than the estimated gold product west of the Missouri, published by Mr. Valentine, of Wells, Fargo & Co.'s Express, who placed it at $30,653,959.

STRIKE NEAR AJAX HILL.—A rich strike was made yesterday in the Bangor mine, situated in the vicinity of Ajax hill, about two miles south of town. The strike was made at a depth of 50 ft., and consists of a 26-inch streak of gray carbonates. Average specimens of the ore were brought to town last night, and assays will be made to ascertain its value, although the appearance of the rock is sufficient to convince even a novice in such matters that it will run very high, probably upwards of $300 to the ton. The Bangor is the property of Messrs. Marsh, Bronk and Woods, and these gentlemen are to be congratulated on the rich strike which bids fair to reward them well for the capital and labor invested.—*Tombstone Epitaph.*

THE following item from the Tombstone *Epitaph* should be read in connection with the article on the "Divining Rod" in another column of this number of the PRESS: A party of gentlemen from Chicago, consisting of Colonels Wm. L. Barnum, Geo. W. Huddleston and J. S. Hall, have been scouring over the hills in the neighborhood of Toomhstone for the last week in company with Mr. Al Peck, of Denver, Col., who has been employed by the first-named gentleman to ascertain with his well-known divining rod where mineral lies. By the prediction of the divining rod the great fissure of the Contention and Goodenough is coming together at a depth of 700 ft. at the south end of the Silver Belt mine. There is also a large body of ore southeast of the Grand Central, and a very large deposit of ore in the Hardscrabble mine.

PROF. WM. P. BLAKE is at Tombstone, Arizona, on the way to Barbee, where he goes in the interest of Copper Queen company, in their forthcoming lawsuit with the Copper Prince.

Working Auriferous Silver Ores.

If rich auriferous silver ores, in which the percentage of gold is high, almost equal to that in silver, should be subjected to a chlorodizing roasting, then impregnated with chlorine gas, leached with water, for the purpose of extracting the gold, and finally leached with a hyposulphite of lime for the silver, it would, although a high percentage of silver might be extracted, result in a yield of gold that would hardly amount to much more than about 50 per cent., more or less. The reason is not easily explained; the gold may be influenced somehow by the base metal chlorides during the roasting, which prevents the gold from being attacked by the chlorine gas. On the other hand, if the base metal chlorides and the chlorides of silver are extracted previous to the impregnation with chlorine, both metals—silver and gold—can be got out very close. On this fact is based Mr. Ottokar Hoffman's gold and silver chlorination process, by which he successfully treated the gold and silver bearing sulphurets of the Tarshish mine of the Colorado No. 2 Company, at Monitor, Alpine county, in this State.

Experimental works are now being put up at St. Louis to carry out this process, under the personal supervision of Mr. Hoffman, who has recently gone there. The mine which produced the ore to be worked is the "Mary Murphy," in Colorado, and the St. Louis company owning it have been unable to make it pay, on account of the low grade of the ore and its peculiarities. Hearing of the Hoffman process, some of the ore was sent to San Francisco for him to work. The result was so satisfactory that he was engaged to come to St. Louis and try the process there. We had an interview with Mr. Hoffman before he left, and he expressed himself as perfectly able to work the class of ores referred to with profit. The ore is pretty low grade, and base, containing a good deal of zinc-blende and galena. It yields both gold and silver. If the process is satisfactorily worked in St. Louis extensive work will be put up there. The ore will probably be concentrated in Frue machines at the mine, and the concentrates shipped. Some description of the process will interest our readers.

The concentrated sulphurets are subjected to a chloridizing roasting in a reverberatory furnace. These furnaces, although old-fashioned stirring furnaces, are considered by Mr. Hoffmann preferable for this class of ores to any mechanical furnace in use, especially to the continuous discharging ones. Those concentrated sulphurets require a very perfect roasting, and he claims that the furnaces with continuous discharge do not give time enough for very highly sulphurated ore to become thoroughly desulphurized. Such high-grade ores require close attention, and the process must be under perfect control of the roaster. However, it does not take near as much time as required by Plattner's gold chlorination.

After the ore has been roasted, it is spread on the cooling floor and sifted, when cool, through a sieve of 10 to 14 meshes to the running inch. The sulphurets are heavy enough, after roasting, to make very little dust during the sifting, so that the inconvenient moistening can be obviated. The lumps are saved till a larger amount accumulates; they are then pulverized in a dry battery and slightly roasted.

Leaching of Base Metals.

The roasted and sifted ore is charged into tanks with filter bottoms, in quantities from two and a half to three tons, and leached with water to extract all soluble base chlorides. The water, if saturated with those base chlorides and some salt, of which generally some is left in the ore undecomposed after roasting, acts on the chlorides of silver like a concentrated brine, dissolving the same. To prevent the escape of this dissolved part of silver, Hoffmann does not admit the water from above the ore, as is usually done, but from the filter bottom, which, by means of a slight pressure, is forced to ascend through the ore to the top of the vat. In this way the concentrated solution accumulates above the ore, and in diluting the same by a stream of water, and permitting the solution to flow out through the filter bottom, the chloride of silver is precipitated on and through the ore, which is then extracted with the balance of the silver. The operation effects the fineness of the bullion somewhat, if there is a considerable amount of lead in the ore, but not materially. The leaching of the silver is done as usual by leaching the ore with a solution of hyposulphide of lime, and precipitating the silver with polysulphide of calcium.

Second Leaching with Water.

After the silver has been extracted the solution of the hyposulphite is allowed to run out till it disappears under the surface of the ore, when clear water is introduced again in order to displace all solution. The delivered ore is then removed from the tank to a dry kiln, where it is left for a time till the surplus water has evaporated. After this it is charged back into the tank still moist. This second handling and drying cannot be avoided, as the ore after leaching is too wet to permit of a free passage of the chlorine gas; but if the works are arranged properly, this partial drying causes neither much delay nor much expense.

Gold Extraction.

The gold in the ore is now in metallic condition, and very bright and clean, permitting a very close extraction. The rim of the tank is provided with a groove, which is open towards the inside, two and a half inches deep and one and a half inches wide. In this groove fits the cover of the tank, leaving, however, a play of one-eighth of an inch around the circumference. The cover being made of inch boards, the staves of the tank will project 1½ half inches above the cover. This arrangement serves in two ways—first, it facilitates the operation to make the cover air-tight with clay; and second, it enables the chlorination to keep a sheet of water one inch thick on the top of the cover, thus making it perfectly air-tight and preventing the escape of gas into the working room during the time of charging the tank with water for the purpose of extracting the gold. The cover is furthermore provided with two pieces of one and a fourth inch gas pipe, six inches long, and a square opening six by six inches. During the time of the impregnation of the ore with gas these pipes are closed with balls of clay. As soon as the charge is ready for the extraction of the gold, these balls are removed, and one of the pipes is connected with the hose of the water tank, while the other, by means of the hose, either with another tank already prepared for chlorizing, or with the ash-pit of the roasting furnace. This is done to utilize the surplus of chlorine gas and to protect the workmen from the very injurious effects of the same. Care must be taken to have sacks placed on the top of the ore right under the water pipe, and kept in place by two bricks to prevent the stream of water working into the ore. The square opening serves for examining the progress of the gas in the ore, and can be closed air-tight by a good fitting cover and clay.

The chlorine gas is generated in a leaden gas generator, which is not heated, as usual, by direct application of fire, but by steam. For this purpose the generator is placed in a tight-fitting box, leaving a space of two inches around the side and the bottom for the circulation of steam. The rim and cover are kept outside the box. The steam enters on one side through a half-inch pipe, while the other side of the box provided with a one-inch exhaust pipe and an outlet for the water.

Whatever steam can be had in chlorination works, this arrangement will prove very convenient and useful. The operator has the temperature entirely under his control. The least turn on the valve increases or decreases the heat, and, of course, regulates the generation of gas. The discharge pipe of the generator projects a short way out of the box. On this pipe is fastened a piece of hose about two feet long, which can be closed with a thumb-screw clamp. The hose lies in a covered trough, which leads outside of the gas-house. In discharging the generator, a small stream of water is permitted to flow through the funnel into the generator, by which the gas is forced through its usual outlet into one of the tanks. When the generator is filled the stirrer is set in motion and the thumb-screw on the hose loosened. In this way the generator can be discharged without molesting or injuring the men. The cover of the generator is closed tightly with clay, and only removed in case of repair. The gas is conducted through a leaden pipe, intersected with rubber hose. Each tank is connected with the main pipe, and can be disconnected by the use of the thumb-screw clamp. The pipe through which the gas enters the tank is independent from that one through which the solution discharges. It is placed higher, and as close to the false bottom as possible. After the gas has been the proper time in contact with the ores, the gold is extracted by water and precipitated in the usual way with sulphate of iron. The gold obtained is of extreme fineness, varying from .970 to .987.

In treating very rich ores, containing, say $700 to $800 gold per ton, the solution carrying out the gold is of a very lustrous yellow color, and the precipated gold accumulates on the bottom is spongy lumps of great specific gravity, some of them showing scales of bright gold, which, under the microscope, might prove to be crystallized gold. There is but very little more time used in leaching rich gold ore than poor.

If the ore is copperous, considerable copper will be carried out with the gold solution, coloring the same green. In order to save the copper, the solution, after the gold has been precipitated and settled, is decanted into the copper tanks; but before doing this it is advisable to draw the solution first into a second gold tank, in order to catch the gold which should accidentally be carried off with the stream, and to leave it there for some time to let the gold settle again.

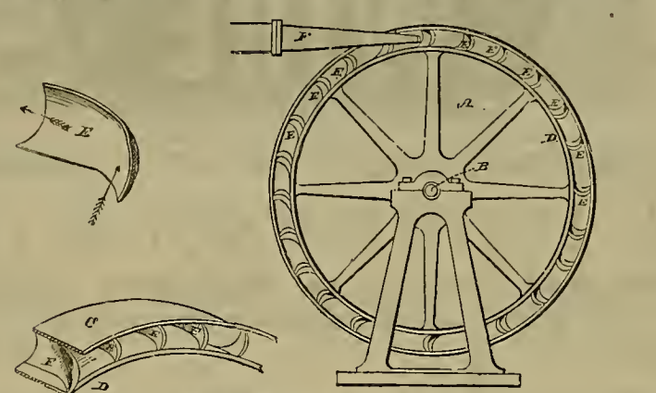
The Divining Rod as a Mining Implement.

[Written for the Press by "Prospector."]

An article in a local paper a few days since referred to the recent use of the divining rod in Paris and London for the detection of hidden treasure.

This instrument, in some form, has been in use from time immemorial, and was probably the rod with which Aaron "struck water" in the desert. It was originally a forked stick of hazel, or a cutting from a peach tree. It can be represented by the letter Y. The forks are held one in each hand, and the stem is supposed to deflect downward whenever a subterranean current of water is crossed. It is claimed by those expert in its use that it is as infallible in the discovery of water as the compass needle is as an indicator of the magnetic pole. However this may be, it has been successfully used by the Central Pacific and Southern Pacific railroads in the discovery of water, and I am informed that their artesian wells on the desert division have been located by the use of this instrument.

Its pretensions as an indicator of the pressure of precious metals dates back a few centuries, but it had then assumed the form of a mechanical contrivance. It was used in the Swiss Alps by the widow of a French surgeon, who claimed the gift of revealing, by this medium, the existence of mineral veins. About the same time it was used in Cornwall, its operations being known as "dowsers." In our own country it was used in the galena regions of the Northwestern States prior to the discovery of gold in California.



NEW HURDY-GURDY WHEEL.

The modern "dowsing rod" is an instrument consisting of two prongs of whalebone uniting in a stem, which terminates in a capping, similar to a rifle cartridge. The contents of this reservoir is known only to the manufacturer or inventor. The instrument is held in the same manner as the hazel switch. In the hands of some persons it is very sensitive, and acts independently of their will, but it is not improbable that the professional adept can make it dip in whatever direction he desires. As an implement for the discovery of mines it is not entitled to the merits claimed by the inventors. During an experience of many years in various mining regions I have never known the instrument to discover a mine of any value. It is true it sometimes indicates a vein or fissure, probably by some electric affinity, but such veins or fissures are usually barren.

If there is an exception to this rule, it is due to some knowledge of geology in the person handling the implement, and the mine could as readily have been discovered by the practiced eye of an expert without the instrument. In Grass Valley, a district abounding in rich veins, it has been used to determine the course of deep veins, but without success following its indications. In Bodie it accomplished nothing of practical value. That it will indicate the presence of fissures, even where covered with a deep layer of drift, has been demonstrated; but it does not follow that the vein is mineralized. There are persons who claim to be "natural magnets," and experience some peculiar sensations when passing over mineral lands; but so far as my experience extends they are not more successful than the professors of the divining rod.

A quartz mining company, once known as the greatest ore producer in California, employed one of these "natural magnets" to trace their lost vein. Through his direction they run a crosscut drift for many hundred feet through a tough and fibrous serpentine rock, at an expense of $30 to $40 per foot. It was impossible that a vein could live in such a formation, and of course nothing was found. The work was entirely unnecessary, as nature and an artificial road had exposed the entire cross section of the serpentine belt at a distance only one-eighth of a mile from and parallel to the underground cross-cut. Strange to say, those who employed the "magnet" were miners of more than 20 years' practical experience, and the magnet was a recent arrival from the marshes of New Jersey.

On one occasion some friends of the writer put a divining rod professor to a severe test. He was taken to a metallurgical laboratory which always contained a large amount of gold, either in bullion or coin. He was permitted to inspect the premises, and was to be returned blindfolded with his rod and search for bullion. The condition was made and kept that no coin or bullion should be removed from the laboratory. As the "professor" was an old hand at the business, it was concluded that he would not "strike treasure" in the safe—its natural receptacle—so all the coin was left in the safe. The bullion was fastened by wires to the under side of a writing table. When all was prepared the divining-rod man was led in blindfold. He was told his position: "You are now at the safe; here are the bullion scales; these are the bookshelves; this is the writing table." The instrument turned away from the safe and spurned the writing table, which had $6,000 of bullion fastened to its bottom. The operator when released from the blindfold said there was no bullion; it had been removed, etc. When shown the bullion and coin, he said his instrument had been diverted by the immense treasures in a bank half a block distant. But the point of the rod had frequently been within an inch of thousands of dollars.

It certainly is strange, if the divining rod be the infallible indicator claimed by its possessors, that it has not enriched some of them. As a rule they reject stage lines and other means of conveyance and foot it over the roads; but this may be to give scope to their "divining rod," and not by reason of impecuniosity.

New Hurdy-Gurdy Wheel.

Michael C. Taylor, of Grass Valley, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a new style of hurdy-gurdy water wheel which is of interest to the mining community. Hurdy-gurdy water wheels are that class which receive the force or impact of the stream of water under pressure upon buckets or flanges on the rim of the wheel.

The features of Mr. Wheeler's invention are a wheel having concentric rims and buckets secured between said rims, said buckets having sharp curved ends, within the face of which they receive the stream, and thence extending with an inclined curved face for conducting and discharging the waste water upon the other side of the wheel. The engravings show the form of wheel and of bucket, and the position of buckets with relation to the rim of the wheel. One figure shows by arrows the way the water strikes and leaves the buckets.

Wheels of this class are generally placed upon a horizontal axis and revolve in a vertical plane, receiving the water from a suitable nozzle above or below. There are two rims to this wheel, *A*, one, *D*, being nearer to the center than the other, *C* but both being of equal width, which is determined by the power of the stream available. In the space between these two rims are secured transversely the buckets, *E*. The degree of excellence in wheels of this kind depends on two things. The first is to provide a good surface for the impact of the water, and the second is to obtain the shape of a bucket or flange which will enable it to free itself of the water instantly and not be impeded by its reaction. The bucket Mr. Taylor has devised has an equal width, in order that it may be inclosed between the rims, *C*, *D*. One end is curved, and its back is so beveled down as to make the edge of the curved end as thin as possible, so that it may with better effect cut into the steady stream as the wheel by its revolution brings each bucket into position. The face of the bucket is curved, the curved lines in the direction of its length gradually approaching straight lines, while in width those at the bottom of the bucket become more curved, so that the lower is in a vertical plane forward of the upper edge. The buckets are secured between the rims, so that their lower edges lie about transversely. This gives to the greater portion of the face of the bucket a direction at an angle with the rims.

The nozzle, *F*, is placed at the top of the wheel, *A*. It lies close to the edge of the rim as possible, and is just sufficiently inclined from the parallel to direct its stream within the curved end and upon the face of the bucket, *E*. On account of the curvature of the end the stream may be directed well within it, and may be given nearly at right angles therewith, thus giving to the bucket the full benefit of a straight force. The water follows the inclined curve of the buckets across the wheel and discharges at the opposite side. Its reaction does not impede the wheel, as by the shape of the bucket its force is retained, though gradually lessened, to the discharge side. Thus the buckets free themselves readily after utilizing to the greatest extent the power of the stream.

The width of the rim and the length of the bucket may be varied with the head of water. Where great force or head of water is available the buckets are made longer in order to utilize its force to the end. By discharging the water upon the side opposite to that upon which it enters it cannot interfere with the stream.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns meet extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. **New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.**

California Wire Works,

(Successors to A. S. HALLIDIE,)

6 California St., San Francisco.

—o—

WIRE ROPES AND CABLES,

Manufactured at our works, guaranteed to be equal in quality to any made, and as cheap, for

MINING AND SHIPPING PURPOSES, ETC.

Wire Suspension Bridges and Aqueducts.

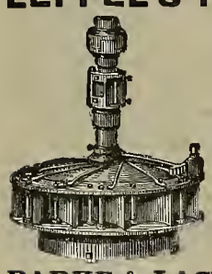
LEFFEL'S IMPROVED WATER WHEEL.



PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for **New Prices,** before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES,

SAVE YOUR GOLD!

—BY USING—

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save more gold than any other method, and double the amount of the same surface of ordinary copper plates. The only plates that have proved durable and satisfactory.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

San Francisco Gold, Silver and Nickel Plating Works,

653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

Send for Circular. EDWARD G. DENNISTON, PROPRIETOR.

Awarded the First Premium at every Fair of the Mechanics' Institute for the last 12 Years.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description. Steel Shoes and Dies that last three times as long as any iron.

WAREROOMS: 92 & 94 Liberty St., New York,

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of **Morey & Sperry** are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm having acquired all the drawings, patterns and machinery of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of **Morey & Sperry,** will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-Class.

MOREY & SPERRY MINING MACHINE CO.

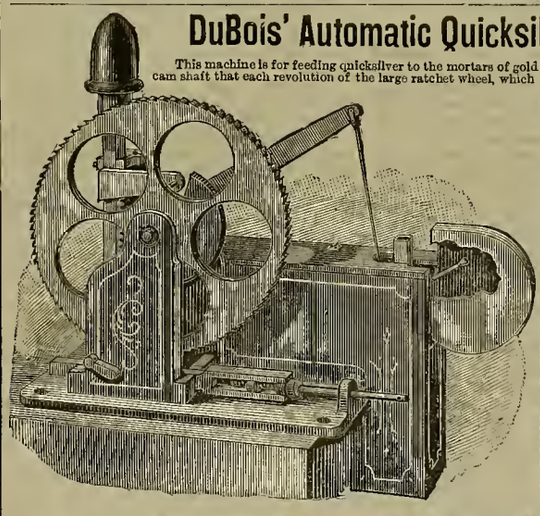
DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.

The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.

A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.

Price, complete, $75.

For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR THE WEEK ENDING NOVEMBER 14 1882.

267 407.—RETURN FLUE VERTICAL BOILER—Patrick F. Duncon, S. F.

267,410.—STRAM PUMP—W. M. Ferry, Park City, U. T.

267,524 —CAN WASHING MACHINE—Jas. O. Hawthorn, Astoria, Oregoo.

268,432.—STAMP MILL—F. A. Huntington, S. F.

267,543 —CLEANING ASH PANS OF LOCOMOTIVE ENGINES—Kilhorn & Smith, Tucson, Arizona.

267,442.—PREPARATION FOR MASKING THE NAUSEOUS TASTE OF MEDICINES—W. H. McLaughlin, S. F.

267,654.—KITCHEN CABINET—J. W. Ross, Santa Clara, Cal.

267,402 —DEVICE FOR ILLUSTRATING FRACTIONS—A. A. Byron, Alameda, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention :

DEVICE FOR ILLUSTRATING FRACTIONS.—Alred A. Byron, S. F., assignor of one-half to James T. White. No. 267,402. Dated Nov. 14, 1882. This is a new and useful arithmetical instructor, and it consists in the employment of a suitable body having a spherical or a somewhat kindred shape made of wood, the body being suitably adapted to be supported in such manner that when properly divided into fractional parts each part or any number, or the whole thereof, may be conveniently upheld or may be removed separately or together for exhibition without disturbing the remainder. The object of the invention is to teach the character and value of fractions by exhibiting the various fractional portions into which the body is divided, and to render such instruction effective and easy by reason of the spherical shape of the body and the convenient means for supporting it, and allowing the separation of any part while the rest remains intact, whereby it may be readily seen what portion the part removed bears to the whole. The best form is that of an apple made to be divided. The children readily learn the fractional shape when seen in this way, as they comprehend the idea better by the object lesson than they do by the mere exhibit of figures.

STAMP MILL.—F. A. Huntington, S. F. No. 267,432. Dated Nov. 14, 1882. This invention relates to certain improvements in rock-crushing apparatus of the class in which a rising and falling stamp falls on the rock. We shall shortly describe this mill in detail with an engraving, so say no more concerning it at this time.

RETURN FLUE VERTICAL BOILER.—P. F. Dundon, S. F. No. 267,407. Dated Nov, 14, 1882. This invention relates to certain improvements in that class of boilers known as vertical or upright boilers, and it consists in certain details of construction by which the water is subjected to the action of the heat passing through it from the furnaces in small tubes, and also in returning through it in similar tubes while the steam drums are exposed to the direct action of the heat as it arises from the furnace.

PREPARATION FOR MASKING THE NAUSEOUS TASTE OF MEDICINES.—W. H. McLaughlin, S. F. No. 267,442. Dated Nov. 14, 1882. This discovery relates to a preparation which is principally useful to disguise the bitter nauseous taste of quinine and other bitter alkaloids. It consists of a peculiar aqueous fluid extract of a certain common herb which grows abundantly in this State.

IT is said that Secretary Chandler, in his forthcoming annual report, will recommend the Life Saving, Revenue Marine and Coast Survey bureaus of the Treasury Department be transferred to the control of the Navy Department. It is thought that, should Chandler make the attempt and succeed, he will follow it next year by asking for the transfer of the Marine Hospital Service, another branch of the Treasury.

CELLULOID is now used for making artificial eyes, and is said to be tough, a bad conductor of heat, and an antiseptic in consequence of the camphor which it contains. It is also susceptible of a fine polish, and on its delicate surface the little vessel or shades of color which help to give expression to the natural eye can be faithfully imitated.

IN an Oregon city retail liquor licenses have been increased from $200 to $1,000 per year. The movement is not a strictly temperance one, but is intended to work the suppression of a few class of saloons where the vilest liquors are sold.

THE celebrated Drum Lumon mine, Montana, has been sold by Thomas Cruse to a London syndicate for $1,500,000.

Notes from Eureka, Nevada.

[From our regular Correspondent.]

Perhaps your readers are not generally aware that Eureka mining district is exceptional in one respect, inasmuch as it is a self-made camp. It has not been aided by the flow of capital that has advanced the interests of almost every other mining camp west of the Rocky mountains. Yet it has attained a prominence that is noteworthy indeed.

Its gross productions of gold and silver since 1869, when the first Richmond and Eureka Con. locations were made, has reached the enormous sum of $65 000,000. Of this amount nearly $40,000,000 came from the mines of Ruby Hill.

It is said that the Richmond Con., Eureka Con., Jackson and Phœnix mines have seen their best days; but there is nothing to prove the statement to be true. Improved machinery will tell the tale; but in advance of practical results it is only fair to state that the Jackson mine has not been prospected, except by tributers, for several years. Water came into the main shaft in quantities sufficient to compel the company to stop sinking, and to the present lowest level the mine has not been thoroughly prospected.

Tributers are employed extracting ore at present, and although working under difficulties, are making good wages.

The same thing may be said of the Phœnix mine.

The K K mine is merged into the Eureka Con., therefore nothing is heard of it. The Albion mine, that has been under a cloud of litigation for a lengthy period, has at last come to the front, and is producing satisfactorily. In addition to the ore bodies noted up to the present time, a fine body of ore is now being stripped in the east upraise. At the breast it is 12 feet thick between the walls, but its extent is not yet known. Every effort is being made to facilitate the extraction of ore, which, however, is so plentiful as to make present means of reduction inadequate. On this account 20 men have been drafted from the mine.

The one furnace now in operation is running without let or hindrance, but the other will not be fired up until the fume arresters are completed and the flue duct can be saved. While this is being done means will be adopted to bring in an extra supply of water, which is greatly needed.

I find that a popular error exists in regard to the extent of the mineral resources of our district.

The report has gone abroad that the mines of Ruby Hill are the only ones that can be made to produce ore in paying quantities. I desire to correct the impression that has thus been created by statements unsupported by facts, and will try to do so by giving to your readers a weekly and faithful account of our mines.

By reference to the Eureka County Assessor's records, it is shown that no less than 300 mines have been in operation in Eureka county since 1869 (three-fourths of which are situated in Eureka district) that have been or are now producing ore. In but few of these have there been a reasonable amount of capital employed for development purposes. It is true that there are two or three exceptions, but where they have occurred the lack of proper judgment or want of experience in exploring in limestone formation peculiar to this section is painfully apparent. It is not to be supposed, however, that out of 300 mines in one district there are not a certain number of failures made for want of finding ore in paying quantities. Such a state of things has never been written down in the history of mines since the commencement of the world. But to illustrate the fact that Eureka is a self-made camp, it is no more than proper to state that as an offset to the $65,000,000 produced in the district, less than $3,000,000 of outside capital has been paid in to accomplish the enormous result. It is not surprising that erroneous reports voiced abroad should be accepted as sterling when it is known that they have been circulated mainly by the very men who are usually supposed to be better informed. Prospect mountain, these men have said, contains no ore but the deposits found upon the surface; developments have since proved to the contrary. The Prospect mountain and Eureka tunnels have brought valuable ore bodies to light from depths varying from 500 to 1100 ft. from the surface. Gen. P. E. Connor, the superintendent, informs me that the trustees of the Eureka Tunnel Co. will, in a few days, publish a full and detailed statement of its affairs for the benefit of its stockholders. The mine is looking well. Ore is being shipped from it at present at the rate of five tons per day, and the assay value of the same is at the rate of $175 per ton, the best average yet obtained on that mine. Yours truly,

J. N. H. JOSEPH.

ELECTRIFIED LILY.—During a storm at Montmaurin, in the upper Garronne, M. F. Laroque witnessed a curious electric phenomenon. Looking toward a clump of lilies, he saw the highest plunged in a diffused violet light which formed an aureole around the corolla. This lasted for eight or ten seconds. After it had ceased he approached the lily, which he found, to his great surprise, wholly deprived of its pollen, while the neighboring flowers were covered with it.—*La Nature*.

Railroad Travel in This Country and in Europe.

In Europe the average speed of railroad trains is 23.12 miles per hour. In the United States 24.31.

In Europe the average fare is 2.74 cents per mile; but wherever there is a large amount of through travel the fare is advanced to an average of 3.02 cents, adversely to such travel. Such a policy to an inhabitant of the United States appears very singular, for here the average is 3.29; while when there is an exceptionally large amount of through travel the fare is reduced to 2.88 cents to encourage such travel.

For number of trains on a single road and for speed England leads the world. From London to Grantham, 105 miles, the regular trip is made at the rate of 52 miles per hour. The fastest train in the United States is the direct line between New York and Boston, which maintains a speed of 38.38 miles per hour. The fastest train in France is that from Paris to Bordeaux, 360 miles in nine hours or 46 miles per hour. The speed of the fastest German train is the same—from Berlin to Cologne. All other European countries run slow, as a rule, slower than in this country.

In France a workman can travel 30 miles in a third-class car on a day's wages; in Italy and Spain from 10 to 15 miles, while in the United States he can travel from 40 to 50 miles in a first-class car for a day's wages.

Railroading in the Central States possesses another peculiarity. While in Europe second and third-class cars are almost invariably rare, in the United States the system of railroad travel is based on two grounds—that it is much easier to run trains with one class of carriages than with three, and that all travelers are, in theory at least, socially equal.

In England nearly all machinery is constructed after much heavier modes than the same class of machinery in the United States, with the single exception of railway locomotives and cars. An American passenger train is usually twice as heavy as a train for an equal number of passengers on an English road. It is now generally acknowledged by the engineers of this country that there should be a reduction in the weight of cars. While in this we are inclining to English practice, English railroad men are fast introducing our style of open cars in preference to their compartment cars.

News in Brief.

ADMIRAL SEYMOUR and General Wolseley have been gazetted peers.

THE past year's vintage in southern California has been the best for 12 years.

DURING October 57,689 passengers arrived in the United States from abroad.

A YOUNG lady has been elected Superintendent of Public Schools in Mono county.

THE six Chinese companies of San Francisco have combined for charitable purposes.

WILLIAM CUNNINGHAM jumped into a blast-furnace at the Birmingham, Ala., rolling mills Saturday.

A STATUTE of 1784, in relation to the observance of Sunday, has been revived in Connecticut and enforced.

SMITH, who was inspired to "remove" his 14-year-old son, was arraigned at Los Angeles, and pleaded not guilty.

CALIFORNIA lions and grizzlies are plentiful near Bear valley, Mariposa county, and have killed considerable stock.

THE British Government has expended $120,000 for the destruction of locust eggs in the island of Cyprus the present year.

IT is denied at the Chinese Legation in Washington that the Chinese Minister and suite are to be withdrawn from the United States.

JUDGE ADVOCATE GENERAL SWAIM decides that the failure of army officers to satisfy any indebtedness fairly contracted would not be a violation of the 61st Article of War.

THE Northern Pacific Express Company will soon begin operations on the railway and steamboat lines in Oregon, Washington, Idaho and Montana, supplanting Wells, Fargo & Co.

THE Secretary of the Navy has issued a circular inviting the presentation to the Department by any skillful person of plans, models and designs for the new steam cruising vessels for the navy.

THE annual report of the Secretary of the Treasury shows the receipts of the Government, exclusive of the public debt, during the fiscal year ending June 30th, to be $403 525,250, and the expenditures, exclusive of redemption of public debt, $257,981,439.

RAINFALL IN TWENTY-FOUR HOURS.

.00	.00	.00	.00	.00	.01	.00

Total rain during the season from July 1, 1882, 26.91 inches.

For The Coming Year.

Our old readers may depend upon an active and progressive career on the part of the MINING AND SCIENTIFIC PRESS for 1883. During the intervening period, to give us further power and vim for keeping up and improving the standard and excellence of our paper, we respectfully urge that as many subscriptions from our numerous worthy and appreciative patrons as possible be forwarded, that the publishers may "rejoice and be exceedingly glad" in their best efforts for the intellectual and material progress of those they strive well to serve and benefit.

Pacific Coast Weather for the Week.

[Furnished for publication in the PRESS by NELSON GOROM, Sergt. Signal Service Corps, U. S. A.]

The following is a summary of the rainfall for each day of the week ending 11:58 A.M. Wednesday, Nov. 22d, for the stations named:

Date.	Thursday.	Friday.	Saturday.	Sunday.	Monday.	Tuesday.	Wednesday.	Totals ...

*Reports missing.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them DEWEY & CO.

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,
No. 252 Market St., S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARAN C. HOAG—California.
L. L. WOODMANSEE—Nevada State.
B. W. CROWELL—Los Angeles county.
L. WALKER—Butte, Tehama and Shasta counties.
E. A. WILLIAMS—San Francisco.
S. E. BAKER—Eastern States.
J. WILTSE, Amador county.

Old Papers Wanted.

Twenty cents each will be paid for a limited number of copies of any of the following Nos. of the MINING AND SCIENTIFIC PRESS, if received soon at this office: No. 1, of Vol. 13, 1866; No. 5, Vol. 18, 1869; Nos. 1 and 26, of Vol. 20, 1870; No. 1, of Vol. 22, 1871. Also, 10 cents per copy for Nos. 2, 3, 4, 7, 10, 11, 12, 13 and 15, of Vol. 30, 1875. If any one who has files of back volumes of the PRESS, which they may like to dispose of at a moderate rate, will send us a memorandum of the same and the price, we may be able, sooner or later, to assist in their disposal.

Apprentice Wanted.

Wanted, a well-recommended, able and steadfast boy, of fair education and good intellect, to thoroughly learn the printing business. None other need apply. Address this office.

To Engineers and Draftsmen.

WANTED.—A good wood engraver. Also, a draftsman, who can make pen and ink drawing on paper or stone. Apply at this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call*. Address L. P. McCarty, 502 Taylor st. Price, $4.

Extra Type For Sale.

We offer Scotch brevier type, (same as used on this paper) for sale in any quantity from 100 lbs. to 1,000 lbs., for 25 cents per lb., if ordered soon. Also, several hundred pounds of nonpareil at favorable rates The type is in good condition and is of a very durable character.

WATER JACKET SMELTING FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN SIXTY of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time to construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished who desired to examine mines and to superintend construction and running of furnaces. Estimates given upon application.

Send for circular.

MINING MACHINERY A SPECIALTY.

Our manufactures of mining machinery embrace every kind of machine and appliance for the mining and reduction of ores.

We have had an experience of more than twenty years in the manufacture and practical operation of mining machinery in Colorado and the neighboring States and Territories.

Our facilities are superior to those of any manufactory in the West, our works having been recently rebuilt, greatly enlarged and completely equipped.

We invite the investigation of mine owners and mill men seeking machinery. We can furnish, on board, at our works, or set up at the mines anywhere in the Rocky Mountain region, on short notice, the following machinery: Cornish Pumps, Steam Pumps, Stamp Mills for Wet or Dry crushing, Pans, Settlers, Agitators, Retorts, Bullion and Ingot Moulds, Reverberatory Furnaces, Bruckner Cylinders, Revolving Roasting Furnaces and Dryers, Melting Furnaces, Concentrating Machinery, Rolls, Crushers, Conveyors and Elevators, Ore Samplers and Grinders, Hoisting Engines, Water Jacket Furnaces, Slag Pots and Cars, Lead Pots and Ladles, Blast Pipes and Water Tuyeres, Blowers, Cupella Furnaces, Market Kettles, Wire Rope, Cages, Buckets, Skips, Ore Cars, etc. Estimates furnished and prices quoted on application. Send for illustrated catalogue.

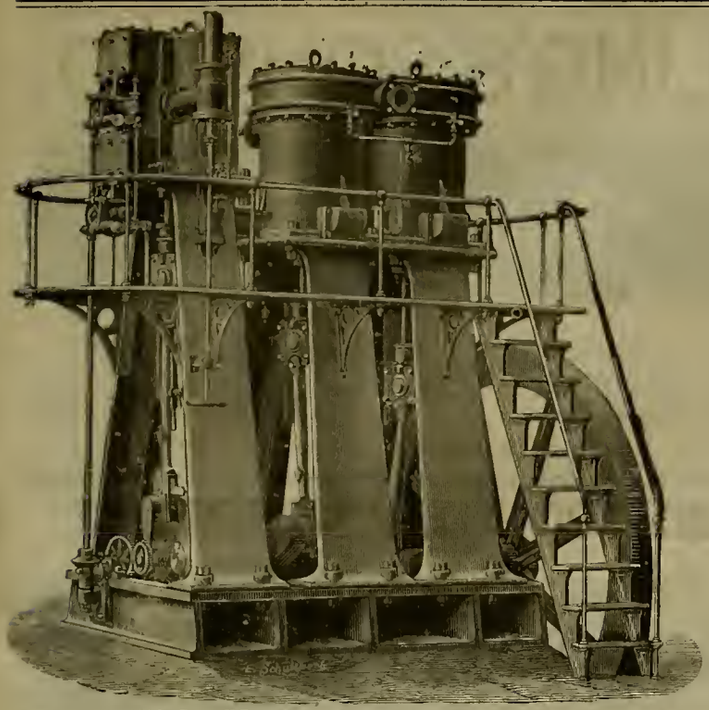
ASTHMA. The greatest proof of the genuine merit of an article can be found in the amount of patronage it receives, and the thousands of testimonials respecting Dr. Hair's Asthma Cure, proves most conclusively that it is all that it is represented to be. DR. HAIR'S Treatise on Asthma and Hay Fever contains a list of cures from every State and Territory in the United States, also from every Dominion of Canada, England and Scotland. Treatise sent free, address Dr. E. W. HAIR & SON, Cincinnati, Ohio.



With Adiustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street, S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

NATIONAL COMPRESSORS and ROCK DRILLS.

EDWARD A. RIX, Agent,

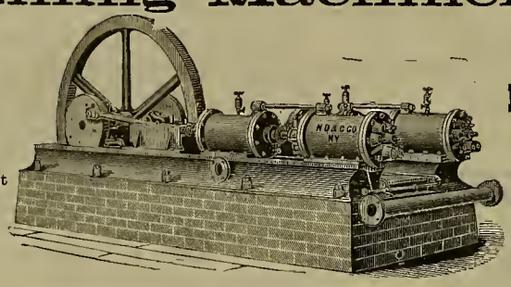
Successor to **REYNOLDS & RIX,**

No. 49 Fremont Street, San Francisco, Cal.

MANUFACTURERS OF AND DEALERS IN

Mining Machinery.

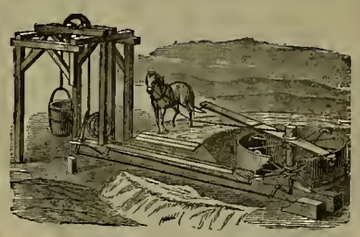
We manufacture the **BEST Air Compressors** Ever driven by belt from Water Power.



Hoisting Rigs.

DONKEY ENGINES For Pile Driving.

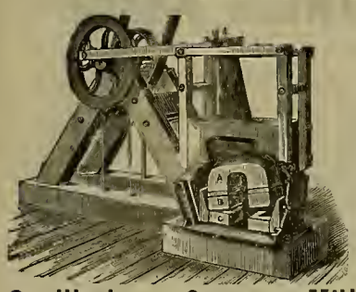
MINING CARS, Ore and Water **BUCKETS.**



MINERS' HORSE-WHIM.

One Horse can easily heist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

MILL AND MINING MACHINERY.



Oscillating Stamp Mill.

Is has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by

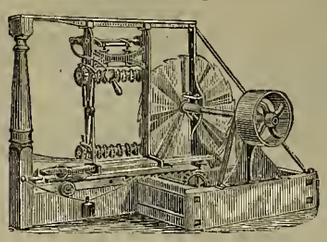
PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in very short time. One machine will concentrate the tailings from a five-stamp battery.

☞ Send for Circulars. ☜



SHINGLE MACHINE.

For simplicity, durability and rapidity of action, thes Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

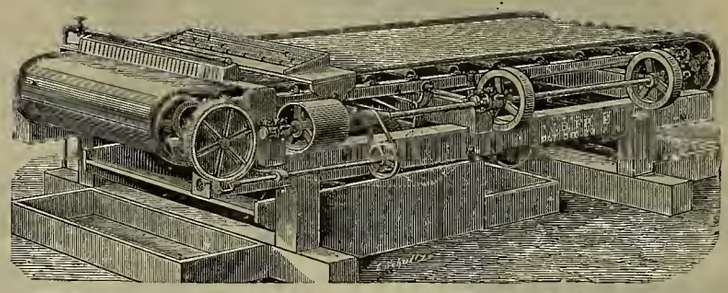
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that *all shaking motion* applied to an *endless traveling* belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make *users* of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of $1,000.

MINING AND SCIENTIFIC PRESS.

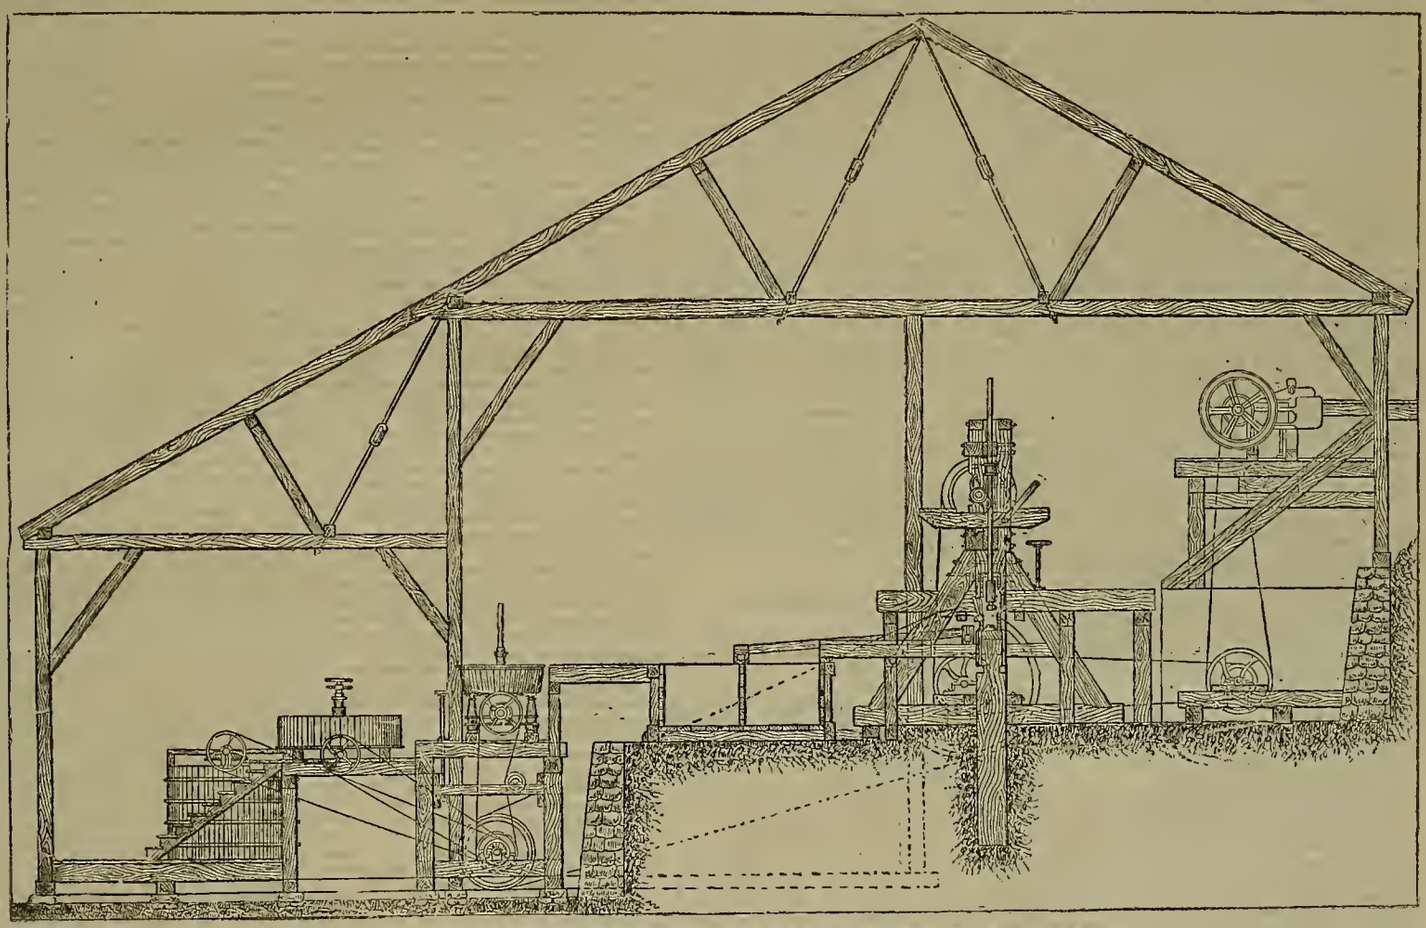
An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, DECEMBER 2, 1882. VOLUME XLV Number 23

General Arrangement of Silver Mills.

The general arrangement of the machinery in a mill working silver ores by the method employed on the Comstock may be illustrated by the drawing on this page, which presents a sectional view of the building, and the more important machines employed in it.

The batteries of stamps, as many as there may be, are arranged in one straight line. Behind them, that is on the feed side, is the breaking floor, where the rock is prepared by a stone-breaking machine, or, in its absence, by hand. Generally the pans are arranged in a straight line, parallel to the line of the batteries, as in the case illustrated. The separators stand in front of the pans, arranged in a parallel line, and on a sufficiently lower level to permit the charge of the pan to run into them. Below the separators are the agitators or other similar contrivances for the purpose of preventing the escape of quicksilver or amalgam. The power is usually communicated from the steam engine or other motor by gearing or belting to a line shaft which is placed in front of and parallel with the line of batteries. On this shaft are pulleys,



SECTION SHOWING GENERAL ARRANGEMENT OF THE MACHINERY IN A SILVER MILL.

When the slope of the ground permits it, large bins are sometimes constructed above and behind the breaker, into which receiver the wagons or cars bringing the ore from the mine may discharge their contents. As the outlets of the bins are on a higher level than the mouth of the breaker, the rock is delivered to that machine without much handling. Such bins, where practicable, are of great advantage in providing a reserve of ore for the mill whenever communication with the mine is interrupted for a time. The batteries discharge the crushed ore upon an apron, or, as in the case illustrated, into a trough or launder, which conveys it to the settling tanks. These stand directly in front of the batteries, though in some mills, for lack of space, they extend along the adjacent side of the building. A platform is usually provided, upon which the pulp may be deposited when shoveled out of the tanks. Some mills are so arranged as to use a car, in which the pulp is moved from the tanks to the pans. This is especially necessary when the tanks are more remote from the pans, or when the latter are arranged in a line at a right angle to the line of the batteries.

In the engraving, *A* represents the ore floor; *B*, rock-breaker; *C*, battery; *D*, tanks; *E*, pans; *F*, separators; *G*, agitators; *K*, line-shaft; *Kk*, cam-shaft; *L*, counter-shaft for rock-breaker; *M*, counter-shaft for pans and separators.

Investigation of Mining Companies.

The San Francisco Stock and Exchange Board has appointed a committee of five to investigate the condition and management of mines listed on the Board. The committee advertises and asks "all persons in sympathy with this movement and possessing information which may assist the committee in its labors to communicate with them in person or by letter, confidentially or otherwise." This committee consists of M. J. McDonald, Marcus P. Hall, Rob't F. Rodgers, Coll Deane and J. M. Goewey.

The only thing we can say about this move of the Stock Board is that it is rather late. If the Board had done this very thing a long time ago, its business would have been much larger, and the mining interests of the State would have been materially assisted. It was a common complaint in the days when mining stocks claimed a larger share of attention than they do now that many swindling operations were carried on which could have been prevented had the Board had a committee such as it has now appointed. All sorts of sharp games were played by managers of such companies, and the brokers, who probably had nothing to do with them, got a bad name for not attempting to prevent the practices which they knew were going on.

A good many companies appeared to have been organized for the mere purpose of having stock to sell. The operations of mining were a secondary consideration. The Stock Board took no steps to weed out this kind of companies or to warn people against them. They seemed to think it was no business of theirs. But the results of this kind of carelessness have now come home to them in reduced business and fewer commissions. People ceased to have confidence in the Boards or the companies.

If the Stock Boards would put on their lists only such companies as they had good reason to suppose were organized and operated as legitimate mining enterprises, the people would soon see that the name of the listed mine was a sort of guarantee of good faith. They would prefer to purchase such mines. The move now being made is supposed to be in the interest of the people against the "assessment mining companies." If assessments are being levied on mines where there is no earthly probability of anything being found, the committee are going to so tell the shareholders, or if the management of certain companies is such as to throw discredit on the mine and to depress its value, we are to be told this also. At least we should so judge by the announcement. We hope for good results from the labors of this committee.

A Glut of Miners in Calico.—The Virginia *Chronicle* has received a communication from Calico, San Bernardino county, Cal., stating that there is not work enough in the camp for the miners already there. This statement has been deemed necessary, as it is reported in Calico that efforts are making in Virginia City to induce miners to go there by representing that work at good wages can be obtained. The Calico miners claim that this is the first move in an effort to cut down wages.

The Hecla Con. Mining Company, of Montana, resumed dividends on the 1st of November, with one of 50 cents per share, aggregating $15,000. Total of dividends to that date, $342,000.

Rapid Growth of Arizona.

Mountains and Valleys Filling up With Settlers.

The rapid settlement of Arizona, says the Tombstone *Republican*, is one of the wonders of the movements of popnlation within the United States. Up to within a very few years this territory was looked upon as a veritable desert in the absolute sense of that term, and none but those of the most hardy natures would venture to set foot within her boundaries and those men mostly bent upon a search for the precious metals. The agricultural settlement in the Salt river valley was the only exception to this rule outside the commercial city of Tucson, the foundation of which was laid at a very early date hy the Jesuits, who, like the more recent explorers, were mainly bent upon wresting from nature her treasures of gold and silver. To-day the whole aspect of this question is changed, and people begin to realize that, notwithstanding the arid and mountainous nature of the country, it is far from being a desert. There have been found by exploration scores of fertile valleys, containing from a few hnndred to many thousand acres of the richest land, that will produce the most abundant harvests of corn, wheat, barley, oats, sorghum, potatoes, and vegetables of all discriptions. Outside these arable tracts there are great valleys, covered with a heavy growth of the most nutritious grasses, where hundreds of thousands of cattle, horses and sheep can be grown to a perfection not excelled by any State or territory in the union. Independent of the lands above named are the broad mesas, mostly heavily grassed, and some of them comparatively well watered by springs and streams, where more stock can be pastured than in the valleys. The valleys and mesas combined constitute permanent sources of wealth that are destined to make Arizona one of the riches States in the world. Even the mountains are mostly grassed to their very tops, and will in time constitute great pasture fields, if not for cattle, for sheep and goats that will add to the wealth of the country. To any one who has seen what well directed labor has done in the Salt river valley, there opens up a future for this territory far grander than ever dreamed of hy the Argonauts who first pitched their tents in Apache land. Were there more water in Salt river the area of good land now brought under cultivation could and would be easily doubled. Unfortunately the water supply cannot be increased, except, possibly, by artesian sources, which is an experiment as yet untried. The lower Gila—that is, below the mouth of Salt river—affords an ample supply to redeem all the fertile bottoms along that river to Yuma, which is now being appropriated in a few of the more desirable localities. Go where one may, throughout this broad territory, miners, farmers and stock raisers are found hard at work developing the latent resources of the country. Men with limited or moderate means can find better opportunities for making permanent homes right here in Arizona than in any other spot in the United States to-day. The hardships and privations to be endured are nothing as compared with what the early settlers had to undergo in the settlement of all but the prairie States of the Atlantic coast, and not so great as in Dakota, Montana, Idaho, Washington Territory, Utah and Nevada. The winters here have no terrors, and the hot weather of the summer is relieved hy the cool and balmy nights which bring refreshing rest after the heated labors of the day. Those who have judged the capabilities of this country by a cursory or hasty investigation, have too often done it an injustice that time and experience will cause them to regret. Arizona is not only a good place to make money in, but a good place to make homes and a permanent settlement.

A New Style of Steamship.—Commodore Coppin, of England, has designed an improved ocean steamship. The diagrams show a triple-hulled screw ship. There are three separate vessels below water, while above one vessel only is seen. The center hull, which is 204 feet shorter than the outside hulls, contains the engines. There are two screws or propellers at each end, either of which can be worked in case the other is disabled, or the two can be worked in unison, thus increasing the power and speed. It is claimed that this vessel will make a voyage from New York to Liverpool in five days. The vessel is designed principally for passenger traffic, all staterooms being above the water line, while if it is required, the vessel can carry as much freight as the *City of Rome*. The inventor says that seasickness in his vessel will be an impossibility, as the three hulls will prevent the rolling of the vessel, even in the heaviest sea. The hulls both forward and aft are pointed; in fact, the steamer can be run either backward or forward with equal rapidity.

An Improved Coil Spring.—A device for equalizing the driving power of a coiled spring, adapting it to drive sewing machines at a uniform speed, has been patented by a Hoboken, N. J., man. In this invention a regulating wheel, which is driven by the coiled spring, has a spiral row of holes on its face from near the center to the periphery. A spur wheel, whose teeth run in these holes, slides on a feather upon its shaft, the outer end of which is furnished with a gear wheel that engages with a train of wheels. Through these wheels the power is applied to the machine, with a gradually decreasing leverage as the force of the unwinding spring decreases.

Railroads Wanted for Mines in Arizona.

From the Arizona *Gazette* we take the following concerning the roads wanted to tap the rich mining camps of the Bradshaws:

A wagon road from this city to Bradshaw basin, via Castle creek and Minchaha flat, has been discussed by the *Gazette*, at intervals, ever since its birth. A year since, or a little more, Mr. Patterson, at that time proprietor of a sawmill, made a trip with his "bull team" to Phœnix, bringing with him some very choice lumber, which met with a ready sale, and returning with a load of provisions. In returning, however, the improvised road was not equal to the emergency, and Mr. Patterson left one of his wagons below the falls on Castle creek, where it still stands. Now, even so far as to the Peck, Phœnix is the natural supply point for all articles of provision and necessities to the operators of mines and other enterprises. The people there recognize that Prescott, even with the additional advantages she may now enjoy from the proximity of the A. & P. railroad, cannot afford to give them the satisfactory prices that Phœnix naturally affords. In fact, all sections interested seem to recognize this fact, save Phœnix herself. At present mining is brisk in the section to which we allude. The Peck is running, the Tiger is being operated, so is the Oro Bell, at the Oro Bonito camp; Castle creek has quite a boom, and capital is opening up the properties on West Hamburg, to say nothing of a hundred minor operations where the sound of the blast is constantly heard, and the dull, steady roll of the arastra proves that there is some object in the labor. These operations are all overlooked by our people. They seem lost in the abstraction over their own internal affairs, and do not seek to reach out and command the trade that awaits them. Prescott people are already contemplating and devising means for constructing a road from Walnut Grove to Castle Creek, which is 20 miles further from them than it is to Phœnix, and over mountains, while to this valley a natural level roadway exists. There is already a fair, natural road to Castle Creek, 45 miles from here. What our people want to do, the merchant, the farmer and business man, is to continue this road to connect with the one in Bradshaw Basin, from Prescott. A few thousand dollars, together with what the miners and merchants in those sections would contribute, would give a good road, close connections between Phœnix and the best mines in Arizona, and bring with it a trade to which the original expenditure must be a mere trifle. It is foolish to talk of narrow-gauge railroads to the mines, or branch lines to connect with trans-continental roads, when our people haven't the enterprise to build 25 miles of wagon road, by which a valuable trade could be secured. Phœnix has many natural advantages, but she will never prove much of a city or commercial center, unless she endeavors, by enterprise, to avail herself of other patronage than that which the topography of the country absolutely forces upon her. Let our people resolve this matter in their minds and see if some preconcerted and effective action cannot be reached in the near future. The Bradshaw mountains are ripe with treasure, which only awaits picking at our hands.

Successful Concentrators.

The most successful attempt at concentration we have yet learned of, has been made with the new process concentrator, operated by Clark and Leavick, at the Lunt mill. The concentrator made a run on low grade London ore, which was supposed to be below anything that would pay. The ore ran only nine-tenths of an ounce in gold, six ounces in silver and six per cent. in lead originally. Seven tons of ore were concentrated into one and three-fourths tons of ore, which runs three and nine-tenths ounces in gold, sixteen ounces in silver and thirty-six per cent. lead. In other words, by reducing four tons into one, the ore has been raised in grade from twenty-five dollars a ton to a value of about $115 per ton. The difference in these figures is in favor of the concentrate, on account of the free gold in the ore which does not assay to its true value. These figures were given ne offhand, and there is a possibility of error, hut they are generally credited, and no doubt are nearly correct. This brings within the list of pay ores a vast quantity of low grade ore at the London, and Mr. Herrick, the manager, is so well pleased that he would like to see the experiment tried on a larger scale. If the further trials indnce confidence, it is not unlikely that a very large concentrator will be built on this plan at London junction. The *Flume* rejoices in the good results so far obtained. Another successful experiment of this concentrator was on Weston low grade ore. Four and a half tons of ore that ran hy assay seventeen ounces in silver and a small amount of gold were reduced to 1,320 pounds of concentrate, worth forty-eight ounces of silver and one and seven-tenths ounces gold, or about $79.50 per ton. These experiments would seem to leave no doubt that the concentrator is adapted to the ores of Mosquito district.—*Fairplay Flume.*

The mines of the Sawtooth country are being vigorously worked this winter. The Vienna company has increased the number of miners in the Mountain King, and the Solace, Nellie and others are to be vigorously worked. The prospect for Vienna next year are indeed the most flattering, and all who remain will reap their reward.

Forest Trees of California.*

Merten's Pacific Hemlock Spruce.

(*Tsuga* [*Abies*] *Mertensiana.*)

hemlock tree! O hemlock tree! how faithful are thy branches;
Green, not alone in summer time,
But in winter's frost and rime!
O hemlock tree! O hemlock tree! how faithful are thy branches!"
German of Longfellow.

Vast forests of this Pacific hemlock extend along the coast from California to Alaska. Farther north it constitutes the main characteristic feature of the Pacific Sylva. This most charming tree of all the evergreens, from youth to prime, is of softened conic outline from dense, broad ground-base, to light and airy leading tip; later on in life of spiry, steeple-top attenuation of branch and stem, throughout richly mantled with the finest feminine delicacy of foliage, yet heautifully infilled with the most exquisite variety and grace hy numerous hairy, slender and pliant tiny litte twiglets, feathered, here in California, with the briefest leaf and thinneet of all the fan-form horizontal expanse of spray known to these trees. This is even more spiry than the Eastern Canadian, and only rounded conic when broken off by storms or far advanced in old age. These tall spruces, farther north, are clad in denser masses of darker green verdure—twigs of no longer, strictly two-rowed foliage, but semi-plumed with longer and more varying leaves clothe them from the base to from 100 to 200 ft. or more; body two to six, or seldom eight ft. in diameter; but here only 60 to 75 ft., and rarely over two ft. through, and in sheltered, twilight ebades altogether more open, lighter green, and delicate, soft gray green or glucous hue, most manifest below or shimmering in the breeze, such sensative forms and foliage in the play of lights and shadows is spirit like, fairy and sportive in the highest degree. And then behold the bright enlivening contrast of lighter vivid citrined-green verdure of new and tender leaf, fringing the new-born spring tips, her dark mantle now adorned, as it were, with new floral ornaments, or rather apart from all illusion—infantile sprays of exquisite beauty; delicate and drooping, confiding and reliant as the innocent babe on the breast of the mother—never yet excelled by any object of decorative art, nor even surpassed in the exhilarating and refreshing odors they exhale—the delight and gladness of youth, the joy of age—rejuvenating others to the enfeebled, traditional restorer of the invalid, grace of the grove, beauty of the lawn! The scattered branches, long and slender, of about equal diameter three-fourths their length, horizontal, or the lower drooping with the easy upward sweep and spring awaiting the wintry snows and storms north; here, perfectly level, and free as the toss of the zephyr itself. Bark of young trees and branches nearly smooth, gray, blotched with lichens; old trees, coarse, rough-furrowed, inclined to a dark shade of red, a very slight bruise, or the scarf removed, reveals a very brilliant, bright pink-purple color. Cones pendant from the tips of very numerous slender hairy twiglets; scales about 30, roundish and thin, slightly furred, included bract on the back of the scale, blunt; cones an inch or more in length, oblong cylinder-like, somewhat pointed; seeds (about two-sixteenths of an inch long), about as long as width of the wing, and this three and one-half times longer—a few nit-like glands on the lower side of the seed. The northern form has the usual deoided spruce drooping habit, as before suggested; leaves more densely set, and even crowded, and so distributed more promiscuously on the upper side of twigs—or less strictly observant of the two-rowed character, for although spirally set, upon a short raised base, and this still left on when the leaves fall away—they usually so twist at the base as to appear two-rowed; line-like leaves, though variable, are often three-quarters of an inch long, blunt, eapgreen above, two lines of bloomy-gray beneath; nenally preserves the dense, low bowing branches from little above the ground, so on aloft, inclosing a neat, warm, open canopy within by the lap and overlying boughs closing at their tops; this greatly serves to keep the brooded soil warm, for the roots are shallow, and in Alaska rest on and cling to rocks with scarcely any appreciable soil at all, simply slop-holes of living and dead sphagnum—but here, altogether dry, only the roots reaching moisture—the sharply conic top at the same time serves to let in the sunlight and air to sweeten these woods.

The thickened lower branches often so abound that much radiation and loss of heat is prevented in winter and heat excluded in summer—tempering the clime—besides her foliage precipitates little moisture, unlike redwoods and their like, and as the snow melts soonest on her boughs, they bend down in the lean-to-style of branch or center-pole and circle-tinted. Viewed all round, it is manifest they shed their drip afar round about; this elegant sheltering foliage thickens deeper in or farther back, and multiplies itself amazingly. It not only divides and conquers the wind at the tips, but by successive subdividing sprigs, continuallly diverges and multifariously mingles the elemental strife, until all its force is fritted away, and the calmed air nestles quietly beneath her peaceful wings; therefore a lodge under these boughs is both warm and dry, fragrant and sweetly ventilated—indeed, constitutes that unsurpassed and ever-living sanitarium for the invalid to which we previously alluded. Camping out and sleeping on these boughs has a north continental reputation for restoring and rejuvinating, accordant with Norwegian and Swedish traditions and customs, where, once a week, the floor must needs be strewn with twigs of spruce or juniper tops. Is it any wonder these refreshing odors inspire the social home circles with all the rural virtues that adorn these—

"Lovely bowers of *innocence* and ease,
Seats of my youth, when every sport could please;
How oft I've listened o'er thy green,
Where humble happiness endear'd each scene!"

And where this old *sylvan nurse* reached her long arms out and took us by the hand, and we self-sufficiently climbed her arms, and, with loud echoing glee, sported among the entanglings; or, with dignified importance of great business in hand, selected the choice bough for the cross-bow, or more primeval bow and arrow of the native. It is noteworthy how admirably this tree rallies and thickens in the top when broken off by the tempest—which full oft takes the conceit out of its too ardent aspirations—nature's testimony that it bears training to any reasonable extent, responsive to the bidding of the master; one of the best shelter trees known, wherever it will flourish at all, whether for the orchard, garden, yards, or for game of all sorts.

In our native wild woods, the cattle and beasts of the forest and field, and the fowls of heaven, find shelter under her shadow; the grouse, the squirrel, the jay and their like, find a constant home in the more darkened head—genial tent-house when storm and tempest roar, secure hiding place from alarm and danger, and ever present night retreat to hosts unnumbered, with the sweetest songsters of the grove.

To dwell on the vast and varied uses at length would carry us too far in detail—a final word on the California form, its timber products, economic, and few other uses must suffice. Contrary to experience and observation relative to most other timbers, the old matured heart-wood is more perishable than the young and sappy polee and branches where they are exposed to the seasons—perhaps because less interstitial separation of annual growths or "shaky" texture with such ready absorption and rentention of water, etc.; hence its almost sole devotion to internal work, securely sheltered from alternate storms and burning suns; for rude raftere, etc., duly seasoned with the bark on, they are singularly lasting and very elastic, with much of the snap and spring of the yew and cedar, combined with a due degree of strength.

Only in the coast forests of California, contiguous to rivers or cold creek banks at the southern limit of its growth, is the Pacific Hemlock Spruce ever found much over two feet in diameter and about 60 or 80 feet high. Up to extreme age it preserves the perfect, symmetrical spire-form, and is altogether less marred by unsightly dead limbs, than its kindred of the East—the same observation applies to Alaska. Perhaps if this tree in our forests, or cultivated in this clime, were more exposed, a somewhat broader conic style would supervene; however, in its native haunts the horizontal, open, and airy branches, subdivided branchlets, and final feathery sprays have the utmost strictly two-rowed leafy plan, the tiny line-leaves about half shorter—certainly the most delicately gauzy, chaste, and beautiful tree it is possible to imagine. In the young state, say from 10 to 40 feet high or more, the bark is relatively smooth and even, branches exactly level, thin, fan-like, long and slender, with cherry-brown bark. These free hearted boughs from the breast are wont to lose entirely the pesked Italian brigand-hat or Alpine style so common elsewhere, not even pending like tassels at the tips save when in young springtime, but toss their entire limbs as lightly and freely to the breeze as the wild deer leaps on the mountains; or, stirred by the gentler zephyr off some sunset shore, vibrating the softest silvery emerald sheen, like a celestial thrill, close along the confines of the invisible, or dimly seen, so ennerved are the tiny leaves of this tree of our earthly paradise that no artistic grace of pencil, or power of pen, can express the charm of every exquisite form and enlivened motion.

M. P. Paul reports in the *Genie Civil* a curious case of galvanization. Pieces of zinc had been put into the workshop boiler to prevent incrustation by the feed-water. After a few days the engine worked with difficulty, and at last would not move. An examination was made and the piston was found to be covered with a thick layer of copper. It was put into the lathe, and in some places which had been worn by use the layer was so thick that the turning was made in pure copper. This is the explanation given: The boiler was connected with the engine by copper tubes. Particles of zinc which were carried with the steam formed with the tubes an immense number of galvanic couples. The piston principally attracted the copper, both on account of its own continual movement exercising an attraction of mass on the molecules, and of the heat (291.2° to 382° F.), which facilitated their permanent deposit.

We learn that the checks of the Columbia and Beaver company cannot be cashed, and that a good many men at Sawtooth who have worked hard all summer cannot get their pay. This is rather rough on the laborers who have spent many months in the mines and mills of the company.—*Ketchum Keystone.*

* From "The Forest Trees of California," by A. Kellogg; published by the State Mining Bureau. State Printing Office, Sacramento, 1882.

Mechanical Progress.

Usefulness of Technical and Trade Journals.—The encouragement of technical and trade journals augurs well for the advancement of manufacturing and mechanical industries. No matter how skilled may be a workman, his fellow craftmen possess secrets of which he is ignorant, and which can, as a rule, only receive the proper dissemination by being published in the specialty or technical papers that are doing so much for the elevation of the American artisans and their numerous calliugs, in which the public is so intensely interested. Every mechanic who prides himself in his particular line ought to subscribe regularly to a trade journal—one representing most closely the branch of work in which he is engaged. This should be read closely and carefully, and the hints and suggestions thrown out must be noted with the view of giving them practical tests. By pursuing this commendable course a greater degree of technical skill is acquired at a trifling expense of time and a small outlay of money. Then, too, a knowledge is obtained as to the better class of new textbooks appearing from time to time bearing on the exact sciences and applied mechanics. Besides all this, the general news of particular localities as to the progress thereof is an especial feature characterizing these papers, of which sight cannot be lost without detriment to the loser. To be well posted is as much stock in trade with a mechanic as it is to a merchant or professional man. The trade journal is fast becoming, under wise and faithful guidance, as much of a necessity as the daily paper. —*Western Industrial Journal.*

Mechanical stokers are being introduced in England. Knapp's mechenical stoker has been introduced by a company in Birmingham, England. The fuel is placed in a hopper in front of the boiler, at the bottom of which is a crusher spindle, which revolves very slowly and carries the fuel to a reciprocating bar, whence it passes to the fire bars, which have an alternate reciprocating motion. As the coal drops on the bars, it has mingled with it a free supply of air, which enters through a perforated deed-plate. Once the apparatus is adjusted, a steady feed may be relied on. It has the advantage of consuming all smoke. Another mechenical stoker is that of McDougall, of Manchester, England. The fire bars have an alternating motion upwards and downwards, and backwards and forwards, the motion being derived from a series of eccentrics on a shaft of Bessemer steel. The fuel is supplied through a hopper, in the lower part of which is a ram, which thrusts it forward at any desired rate. When the fuel enters the furnace it is received upon perforated plates, which, from their position, are kept at a red heat. In this way the fuel becomes ignited before being pushed on to the fire bars, an arrangement which commends itself at once to the practical eye. The system admits of the poorest fuel being burned without creating smoke.

A New Steam Engine.—Two Tennesseeans have patented a new steam engine which aims to economize steam and maintain a constant equal pressure on the driving shaft, accomplishing the idea involved in the ae yet impracticable circular engine. It is an improvement on those engines which have more than one movable piston working in the same cylinder, each separately connected by the crank. The new engine has three pistons in the cylinder, and the rod of the central one passes through the center of the inner piston. The rods of the outer piston also pass through the wires, secured to it at equal distances from the rod of the center piston; these rods are not fastened to the center piston, though they pass through it. By this system the movements of the outer and inner pistons are steadied. The central and outer pistons are forced apart in opposite directions when the steam is let in between them through the port, until the exhaust port allows it to escape; and when it is admitted between the central and inner pistons, the former is moved back, going in one direction, while the end pistons move in the other; and as the cranks of the central and end pistons are set opposite, the crank shaft is at the time pulled and pushed in opposite directions by the movement of the three pistons, and the strain upon it is equal in both.

Iron Supports.—Unprotected iron posts, girders or other iron supports, are out of place in mill construction. In the nature of work done in mills and the structural material thereof a fire proof mill is out of the question. Subjected to heat, an iron girder will warp and let down before a wooden one would be well fired. Cast iron cracks the instant water touches it. Iron posts and girders are sometimes covered with wood, terra cotta, Teil lime composition or other non-conducting material to protect them from fire. There is a method of terra cotta construction with wrought and cast iron frame for the interior of mills, in which all the constructive iron work would be protected, and the use of inflammable material would be discarded for all interior purposes, in so far as it pertains to the building. Much attention is being paid to this matter at this time, and it is to be hoped that some device will ere long be introduced which will meet with the general approval of architects and builders.

Edge Tools.—All cutting and piercing edge tools operate on the principle of the wedge. A brad-awl furnishes an example which all can readily understand. The cutting edge of the awl severs the fibers of wood as the instrument enters, and the particles are compressed into a smaller compass, in the same manner as when a piece of wood is separated by a wedge. A chisel is a wedge in one sense, and an ax, drawing-knife, or jack-knife is a wedge. When a keen-edged razor is made to clip a hair or remove a man's beard, it operates on the principle of the wedge. Every intelligent mechanic understands that when a wedge is dressed out smoothly it may be driven in with much less force than if its surface were left jagged and rough. The same idea holds good with respect to edge tools. If the cutting edge be ground and whet to as fine an edge as may be practical with a fine-gritted whetstone, and if the surface back of the cutting edge be ground smooth and true, and polished neatly, so that one can discern the color of his eyes by means of the polished surface, the tool will enter whatever is to be cut by the application of much less force than if the surfaces were left as rough as they usually are when the tool leaves the grindstone. All edge tools, such as axes, chisels and planes, that are operated with a crushing instead of a drawing stroke, should be polished neatly clear to the cutting edge, to facilitate their entrance into the substance to be cut.

Tires of Mixed Metals.—The Chamouni works have recently begun to manufacture, says *Engineering*, tires of mixed metel—half iron and half steel—and which, it is claimed, will have the hardness of the latter without its fragility. The body of the tire is composed of a ring made of pieces of puddled steel, and inserted between two hoops of fine iron, which form the outer sides of the section. The whole is welded together by the hammer. The principles of their manufacture are as follows, but they have not been developed very far as yet: A bar of fine iron, which is to serve as the core, is first rolled, and then a hoop of fine iron is put on at each end cold. One of these hoops is afterwards to form the flange, and is composed of three coils of equal size. The other is formed of a single coil, and is to make the outer face of the tire. Wedges of puddled steel are then placed obliquely in the space between the two hoops, thus making so many spirals inclined on the axis of the tire. The arrangement brings the wedges together when the hammer is applied, and thus a complete welding is obtained. The wedges are cut from rolled bars; they should be of hard steel, but yet soft enough to weld easily with fine iron. The round pieces thus obtained are forged and welded with the hammer. Four heats are requisite to obtain a ring like those used in the ordinary processes. The welding is completed by the rolling, and it brings the inside core to such a small thickness that it disappears altogether in the boring.

Misdirected Mechanical Ingenuity.—Imprisoned criminals have accomplished most astonishing feats in their efforts to escape. A large proportion of a certain uneavory class of literature consists of the recital of feats of this character. These men, it is true, have nothing else to divert their attention, and are impelled by a motive stronger than the desire of gain in the prosecution of their purpose. An instance of this kind, which occurred very recently, is a notable example of difficulty overcome. An imprisoned convict, without tools or material, contrived to manufacture a key, with which he opened difficult locks, and effected his escape in spite of the watchfulness of his guards. He scraped lead from a water pipe which ran through his cell, made a fire of splinters from his furniture, melted the lead in his spoon, and cast the key without attracting the attention of his watchers. Men in similar condition have performed prodigies in the way of cutting iron bars, drilling through iron doors, breaking through heavy stone walls, constructing ladders, weapons, keys, files, saws, hammers and other tools. They have tunneled long distances beneath deep foundation walls, and accomplished feats which would be regarded as difficult even with the aid of the best implements. It is said also that the finest and most perfect tools known to mechanical experts have been fabricated by criminals in order to effect their depredations upon society.

Responsibility.—Nothing takes the pride of labor and its results out of a man like divesting him of responsibility. The minute you make a machine out of a man into whom God has breathed the breath of life, and given brains and sympathy to, that minute you deprive him of the greater part of his usefulness. This is why public employees and the employees of large establishments are so spiritless and indifferent. The red tape by which they are surrounded, and hampered, and depressed, takes away all their individuality; it makes them mere wooden men, whose places can be filled for less money by cucumber pumps. If you want to get all there is in a man out of him, invest him with a sense of responsibility, make him feel as if he was an intelligent creature, and responsible for what he does or does not. To this fact may be attributed the intellectual superiority of the graduates of smaller shops, where red tape is unknown. But don't mistake by thinking red tape and system are synonomous. Red tape is system carried to an unintelligent and unreasonable extreme. System is order in its highest degree; that is, combined with good sense.—*Phila. Enterprise.*

Scientific Progress.

Practical Scientific Research.

There is a growing conviction among thinking men that money is well spent in promoting really practical scientific investigations. The number of obscure points which are daily brought to the attention of busy men is much greater than might be surmised by those not called upon to meet industrial and commercial questions. The busy engineer, mechanic, electrician and chemist are sure to meet problems of great importance at almost every turn, and many are the regrets that they express that the pressure of necessary routine work renders it impossible for them to study, and perchance solve, some of the questions they are forced to ignore.

The more wide-awake business houses are beginning to see the benefit to be derived from a thorough study of processes for manufacture, from more carefully made machinery, from a more thorough utilization of mechanical and chemical forces previously wasted, and from the positive guaranty which a competent expert can give that the goods they manufacture and sell are of exactly the quality demanded.

But few business firms, however, are willing to go so far as to employ men and furnish facilities for the more elaborate and generally useful investigations; such work has usually been performed by college professors.

Notwithstanding the eminent ability of many of the men who have thus contributed to science, it must be admitted that their results are frequently more or less unsatisfactory. For this there may be several explanations; college professors are often overworked; they are often embarrassed for want of means to procure necessary books and apparatus, and, lastly, they do not, as a rule, mingle freely with the busy practical men to whom industrial and scientific questions are daily being presented. The consequence is that very many scientific professors are devoting themselves to what they term "pure research," and are carrying their theories far beyond the limits of usefulness and common sense. It seems to be true that we must look outside the colleges for a large share of the practical scientific work now waiting to be done.

Much can be accomplished if each well-trained worker will give a small portion of his own time, outside of business hours, to the investigation of some one question which he deems of real importance. Let the work be done without haste, thoroughly, conscientiously and without regard to preconceived theories; let results be minutely recorded when obtained, and, finally, let all be carefully digested and printed in some wide-awake journal for which it is appropriate.

The various scientific and trade associations can do much good in the same direction by setting apart moderate sums of money to be judiciously expended for the promotion of scientific and practical investigation of the various questions presented. Most societies have among their members men who are fully competent to conduct elaborate and useful experiments, and derive therefrom results of real value to all. It is a good sign when each work is encouraged by associations of practical men, and we are glad to note that many societies now have funds, the proceeds of which are employed for the encouragement of original research upon practical questions.—*The Sanitary Engineer.*

Light in Vacuse.—The earliest attempt to obtain light by incandescence in a vacuum was made by King in 1843, who applied continuous metallic and carbon conductors, and heated them by the electric current in a Torricelian vacuum. He was followed in 1848 by Staite, who used an iridium or an iridium and platinum wire, and enveloped the holder in glass or some other nonconductor. In 1872 Konn employed graphite, and rendered it incandescent in an atmosphere of nitrogen, in which there was no wasting away of the carbon. The same principles have been followed, but with greater promise of success, in the more recent attempts of Edison, Maxim and Swan at producing illumination by means of incandescence.

Ozone, says R. B. Warder, has been largely advertised within a few months as a new preservative for all kinds of animal and vegetable substances. The gas is produced by the combustion of a fine, dark powder of cinnamon odor. This substance consists of sulphur mixed with a little carbonaceous matter. On burning, only .09% of ash remains. The so-called "ozone" is sulphurous anhydride, whose destructive action on the germs of fermentation has long been well known.

Torpedoes Doomed.—The principle of the induction balance of Prof. Hughes has been utilized by Captain McVoy, in constructing an instrument by which the presence of a torpedo, anchor, electric cable, metallic portion of a wreck, or other metallic body in the water is detected by a telephonic communication. On approaching such a body, vibrations are produced in the instrument.

Does the Sun Lose Its Heat?—In a paper read by Dr. C. W. Siemens before the English Royal Society lately, the ground was taken that all the heat and energy sent from the sun find their way back to the great solar center, which thus suffers no diminution of its forces.

The Color of Pure Water.

Considerable difference of opinion as to the color of perfectly pure water has hitherto prevailed, and the investigations of Mr. Victor Meyer, a German experimenter, may therefore not be uninteresting. In the course of his experiments he found that the color of perfectly pure water is neither blue nor green, but a shade between the two. In order to demonstrate this, he took 5 glass tubes, about .16 inch in diameter and about 5 feet in length, which he connected by means of rubber tubing, thus forming a tube about 25 feet long. Both ends of this tube were closed with glass plates fitted in metal sockets, the latter being furnished with brass nozzles for filling the tube with water. The tube itself was placed in an exactly horizontal position and covered with black cloth. Upon looking through the tube, the field of vision appeared perfectly colorless, the cloth and the metal sockets preventing the color of the glass from exerting any influence. Upon filling the tube with distilled water, however, an intense bluish-green was observed, which he considered to be the color of perfectly pure water.

Two theories have been advanced to explain the blue color of water when seen in large masses, one, held by Professor Tyndall, being that small solid particles suspended in the water do not reflect the lower or red rays of the spectrum. According to the other theory the color is due to the absorbent action of the water itself on the white light before and after reflection by these particles. The results of experiments made by Mr. John Aitken, and presented to the Royal Society, England, show that the latter theory is probably the more correct one. The greater the number of white reflecting particles the greener the water appears to be, and hence the gradual deepening of the green to blue as the shore is left. The waters of Lake Como owe their darkness to the absence of reflecting particles, as Mr. Aitken ingeniously proved by scattering finely-divided particles of chalk in the center of that lake, thereby producing a very brilliant blue. The brilliancy depends on the color of the particles, and is greatest with white particles. Among coral reefs, which are generally strewn with white sand, the water also takes a very brilliant blue or green.

Effect of Sunlight Upon Glass Surfaces.—The action of sunlight on colorless and colored glass—both polished and rough—is so marked as to have received the special attention of chemists. Very perceptible changes have been observed; that is, from colorless to yellow, and from light yellow, green or blue to the darker or mellow shades of those colors, and specimens of coffee-colored glass are instanced, which, in the space of only five years, had materially changed to rose and amber colors. It is thought that the rich, mellow tones so much admired in the old and richly stained cathedral windows is due to the action of the sunlight in a long succession of years in toning down what were most probably comparatively bright or harsh colors originally; the action, it is supposed, may be a photo-chemical one.

A Printing Press Run by Solar Heat.—Among the attractions of a recent fete in the Tuileries Garden, in Paris, was an apparatus for the concentration and utilization of solar heat, and, though the sun was not very brilliant, this apparatus set in motion a machine which printed several thousand copies of a newspaper entitled the *Soleil Journal*. The sun's rays are concentrated in a reflector, which moves at the same rate as the sun, and heats a vertical boiler, setting the motive steam engine at work. About 15 years ago Prof. Mouchorn, of Tours, began the construction of an apparatus for the utilization of solar heat, and his experiments have been continued by M. Pitre. A company have now constructed a number of apparatus of different sizes. It is to be evident that in a country of uninterrupted sunshine the boiler might be heated in 30 or 40 minutes. A portable apparatus could boil two and a half quarts an hour.

A New Carbon Arrangement.—The following description is given of a new electric lamp recently introduced by Mr. Seligman, of Paris. To each of the carbons is intimately attached along their sides a glass rod. Both rods come together horizontally, actuated in their approach by a spring. Between the glass rods there is a stopper of glass, which is heated as soon as the arc is established in such a way that the rods yield gradually to the pressure of the springs, and keep the carbons sufficiently apart to insure a steady light.

Still Another.—A new lamp, invented by Captain Redivanowski, was lately experimented with in St. Petersburg. The lamp is composed of a small rod of lime or magnesia, containing a certain quantity of carbon, or else of a very thin thread of carbon covered with a coating of lime or magnesia stem, which gives, it is said, a fine light, similar to the Drummond, but more intense. The quantity of electricity necessary to feed each lamp, it is claimed, is less than for the Edison or Maxim; it is, besides, simpler than others and requires no vacuum.

Burning Gas Without Flame.—At a late soiree of the Secretary of Chemical Industry, held at Owen's College, Mr. Fletcher, of Warrington, England demonstrated the possibility of the combustion of gas without visible flame, the heat obtained from a quarter-inch gas pipe being sufficient to fuse iron into drops.

Mining Share Market.

The principal thing in connection with the stock market is the appointment of the Mine Inspecting Committee, which we refer to in another column. The Union Consolidated south drift on the 2,900 level will soon connect with the northwest drift on the same level of the Mexican. There is now hut 50 or 60 ft. of ground between the ends of the two drifts. Next week the men will begin the use of signals in hlasting. They will thus he enahled to continue working on hoth sides till the connection is completed. The importance of this connection is well understood hy all mining men, he new pumps heing manufactured at the Fulton foundry in this city are about completed. The work of putting in these pumps will he commenced in ahout a month from the present time.

The Ophir-Mexican winze, helow the 2,900 level now lacks hut about 40 ft. (four weeks' work) of the 3,100 level. The stratification is again about vertical. Many seams of clay and quartz are heing encountered. The Ophir folks are now putting in some new gear on the surface. Several of the wheels moving the pumping apparatus had lost cogs at various times and were generally pretty well worn out. The pumping apparatns helow ground is also heing overhauled.

At the Consolidated Virginia they will next week resume work in the drift on the 2,500 level which is to connect with the north drift of the Best and Belcher. This north drift is now out ahont 475 ft. Here will soon be made another very important connection for ventilation, drainage, and as basis for exploration.

A MINER IMPRISONED IN A CAVE.—Jim Patterson, a miner of long residence in this section, came near meeting with a horrible death last Saturday. He was engaged with his partner, Larahee, in running the Excelsior tunnel, which is located on the opposite side of the mountain from Monte Cristo. At the time of the accident the men were getting ready to replace a false set of timhers. While digging around it the set suddenly gave way, letting fall from ahove a massive heap of loose dirt. The end of one of the falling timhers caught Patterson in the side, pinning him fast to the ground. The dirt piled on top of him, rendering his position very painful as well as critical. Larahee endeavored to release his comrade, hut soon concluded that it would he useless to attempt it without assistance. So, telling Patterson to he of good cheer, he started for Monte Cristo for help. There the imperiled man was left alone hundreds of feet helow ground, not knowing what moment another cave might occur and crush him to death. However, Larahee finally returned with a number of men, and after six hours of imprisonment Patterson was dug ont. Beyond a general hruising, he escaped injnry, and will probably be all right again in a few days.—*Sierra Tribune.*

IT is reported that J. L. Sperry, of the Big Trees, offered to donate his iron mine situated near Murphy's, Calaveras county, to the railroad company, as an inducement to the company to hring the railroad through Murphy's.

THE Homestake Mining Company paid their regular monthly dividend of 40 cents a share on the 25th inst., aggregating $50,000. Total of 51 dividends, $1,712,500.

The Transit of Venus.

One of the most important astronomical occurrences of the century will take place on Wednesday next, the 6th of December. To the unaided eye or unscientific mind, it will pass without notice. But to the astronomer the event will he one of the utmost importance. What he hopes to gain hy it is a true astronomical unit or celestial yardstick by which astronomio computations can he correctly made. This unit is the exact distance from the earth to the sun. That known, the radius of every orhit, the distance of every star, whose smallest motion is discernahle, and the diameter of every planet can he determined.

The work of determining this unit is exceedingly difficult, hy reason of its minuteness. It is equal, in that respect, to the measurement of the angle of a single hair at a distance of 800 feet. Even if our instruments were perfect, errors will arise from the uncertainty of even the hest trained human eye. Hence many different obsevations must he made to avoid errors hy ohtaining a large average. To accomplish this end ahont 100 transit expeditions have been organized. The importance of correctness in the unit will be seen when it is stated that the nearest fixed star is 366,000 times the distance of the earth from the sun, and an error of, say 250,000 miles in the unit, must make that error 366,000 times as large when applied to the star, or nearly 93,000,000 miles. Hence it is no extravagance of expression to pronounce the present effort an attempt to solve one of the sublimest problems known to science.

OVER ONE HUNDRED POUNDS OF GOLD.—Three huggies, each containing two men, drew up in front of Decker & Jewett's hank yesterday. The men were armed with shotguns and revolvers. Their purpose was not to rob the hank, hut to deposit ahout $22,000 in gold which they had hrought down from New York Flat. The gold was the result of the last clean up in the Nevada Company's placer mine, in which the six men are owners. There were 1230 ounces of the metal, and it is worth from $17 75 to $17 80 an ounce. It will he sent hy express to the Mint at San Francisco. The names of the men above mentioned are W. M. Snow, H. A. Conwell, Daniel Foss, Charles Foss, Robert Elliott and Wan. Wetmore.—*Marysville Appeal.* To this the Nevada *Transcript* adds the following: It is a great fuss over a small thing. Larger lots of gold from the hydraulic mines pass through this city every three or four days, in fact such things are so common up this way that the newspapers seldom note the shipments unless some unusual incident is connected with them.

YIELDING A STREAM OF GOLD.—The Alhambra claim, near Kelsey, owned hy Redd, Ballard and Weatherwax, of this city, is still turning out fahulously rich ore, according to all accounts, from which they are pounding ont in the neighborhood of a thousand dollars a day with a hand-mortar. In two shafts, and for nearly 200 feet along the ledge, a large amount of this extraordinary ore is in sight. Good judges estimate that there is fully one hundred thousand dollars' worth exposed and to he had for the taking.—*Mountain Democrat (El Dorado Co.)*

THE Grand Junction in the Grand River valley, on the Utah extension of the Denver and Rio Grande railway, 425 miles from Denver, has opened for business.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

A GOOD PROSPECT.—*Dispatch*, Nov. 25: We learn from Mr. J. P. Chizeh, who is engaged with Mr. C. Peters in prospecting the extension of the old Good Hope mine near town, that the prospects are very encouraging. The shaft is now down about 45 ft, at which depth the lode is about 5 ft wide, and it is thought that the rock will average at least $6 per ton.

KELLY.—*Ledger*, Nov. 26: Last Saturday we paid a visit to this mine, situated in Hunt's Gulch, about three miles south of Jackson. Six months had elapsed since our previous visit, and during that interval, notwithstanding that the mine had been at a standstill for several months, a large amount of work has been done, so much so that we were scarcely able to recognize the interior workings. The main point of operations is in the first drift, where a ledge 12 ft from wall to wall has been opened up. This ledge runs almost due north, or lengthwise across the claim. A large quantity of rock from this ore body has been stoped out, and run to the mill. From the three stopes it is an easy matter to take out rock enough to keep the mill running steadily—about 40 tone per day. As regards the gold-bearing character of rock, we cannot venture an opinion. From outward appearance, the quartz seems of fair grade. It certainly carries a heavy percentage of sulphurets, but of their gold-yielding properties we cannot speak with certainty. We are informed that they assay from $60 to over $100 per ton, and as the mill, when steadily running, turns out about one ton every 24 hours, this of itself is quite an item of revenue. The mill has had a run of nearly a month, without counting stoppages. A clean up has been made, and something ought to be definitely known concerning the paying or non-paying character of the quartz. The ore is low-grade; there is no difference of opinion on that point, but the facilities for extracting and getting it to the mill are such that if it surrender $2 per ton in free gold it can be profitably worked. Judging from the looks it ought to yield that much. Nearly 30 tone of sulphurets are being hauled to the Amador reduction works, at Sutter Creek, for treatment. The mill was idle at the time of our visit, for lack of water, but it was expected to start up again last Monday. Twenty men are employed about the mine and mill.

SOUTH SPRING HILL.—The shaft has reached a depth of 4,200 ft, and is still sinking, with three eight-hour shifts. It is intended to sink to a depth of 800 ft before drifting for the ledge. Small bodies of quartz have been cut lately, but nothing of consequence.

MISCELLANEOUS.—The small pipe of C. D. Horne's ditch, which carries the water to Murphy's ridge, has been replaced by a 24-inch pipe, which will carry 500 inches of water. This will supply the Kelly mine and leave abundance for mining operations on Murphy's ridge, where lack of water has long been a serious drawback to prospecting.

CALAVERAS.

SALE.—*Echo*, Nov. 22: The Potter mine may be expected to change hands at any time, as there are parties from below negotiating for the purchase of it.

INVINCIBLE.—Parties will begin operations in a few days on the Invincible. It is the intention to commence sinking a shaft immediately.

BRUNNER.—Reed & Co. are busily engaged in sinking a shaft on the Brunner mine. As the shaft attains depth the ore increases in richness. The company intends to start several arastrae soon.

POTTER.—Work is going on briskly at the Potter mine, and with every indication of success. The company has now on the dump nearly 400 tons of ore, which, by the usual process of working, will yield from $12 to $15 per ton.

GOLD CLIFF.—The Gold Cliff mine is producing bullion at a rapid rate. The accumulation of amalgam on the plates is so rapid that it is necessary to clean them daily, and the proceeds of each cleaning is about $400. It seems to us that the above statement ought to be sufficient proof of the gold-producing qualities of the celebrated Gold Cliff mine.

STICKLE & BENNETT.—The Stickle & Bennett mine, which, it will be remembered, joins the Gold Cliff on the north, and is without doubt an extension of that famous mine, is now being worked by one of the prospectors, and is prospecting splendidly. Preparations are now making to work a few tons of ore in the arastrae, and if the result is satisfactory, a 10-stamp mill will be erected as soon as possible.

PORTER.—The shaft on the Porter mine has reached a depth of nearly 75 ft. The rock is hard, and the process of sinking necessarily slow. Superintendent Scribner informs us that he has purchased an Ingersoll drill and an air compressor at Virginia City, which will arrive in a short time, and will immediately be put in operation in the mine. Mr. Porter, the owner, is at present negotiating for a 20-stamp mill at Whisky Slide. Rich developments may he expected in the near future.

ARCHIE BOLAND, the great mining expert, came up from San Francisco on Monday, for the purpose of looking at the Gabriel mine, with a view of purchasing the mine if the indications are favorable.

SHUT DOWN.—Calaveras *Chronicle*, Nov. 24: The Corral Flat mine has ceased to be worked. The pump has been taken out and the diggings allowed to fill with water. The mine has, doubtless, shut down for good.

MILL.—Calaveras *Prospect*, Nov. 23: Brown & McSarley have lately erected an 8-stamp mill on their gravel claim, up Chili Gulch, at a cost of about $2,500, and we understand they intend running a single drift as far as their ground extends, then breast back. This claim stands second to no drifting claim in the county, and bids fair to prove for a rich yield in the near future.

EL DORADO.

PROSPECTING.—Georgetown *Gazette*, Nov. 23: Milo Knox and J. M. Collins have begun work upon the Alpine mine, southwest of town. They have started a drift on the lode, which will take them in about 75 ft deeper than the mine has been prospected. The Alpine is a very promising mine, and we are pleased to see its owners taking this most desirable step towards its development. Messrs. Keefer & Watson, of this place, have a force at work driving a tunnel to tap the Gen. Mead gold and silver lode, helow Garden valley. They expect to tap it at a depth of 100 ft. This is the sort of prospecting we like to see. There are many promising mines on this Divide waiting only for capital and enterprise to open up and extract their wealth.

MILL CITY ITEMS.—*Mountain Democrat*, Nov. 25: Our regular correspondent, writing from Mill City, Mt. Hope, says: Work still goes on here, notwithstanding the cold nights. We rise in the morning to find that old Jack Frost has visited us during our slumbers, and has left a crystal sheet over all the standing waters and along the edges of the Consumnes river. This retards the work in the mills at night somewhat, by ice gathering in the pipes, yet they keep hammering away, and long before the sun reaches the meridian all traces of ice have disappeared. The two mines that were owned by Mr. Driesbach, and bonded, one to J. E. Lyons and the other to B. G. Parlow, have both made a run and cleaned up about $20 per ton, and both have been purchased by the bondees since I last wrote you. This I have from headquarters. There will he three 4-horse teams from Mud Springs here to-morrow to haul ore from the mines to the mills. It is the intention of the companies to build a tramway in the spring, which will he a great saving of expense in getting ore to the mills. The mill owned by the New York company will he ready to start up in about 15 days. H. H. McClellan, the superintendent, thinks his tramway will also be ready in that time.

INYO.

A GENERAL FIRING UP.—*Independent*, Nov. 28: The three most important smelting furnaces of Inyo will be in full blast by the time this issue reaches most of our readers. Supt. Fitzgerald, of the Lookout, will fire up the works next Monday or Tuesday, with ample supplies of ore, coal and wood for at least a month's run. The Defiance furnace at Darwin, according to our best and latest information, was to start up to-day on a general clean-up of ores, slag, flue-dust, etc. We are not informed as to how long the run will be continued, but according to a promise from Supt. Gurman, will have something more definite in time for next week's issue. Lastly, and of more immediate interest locally, the new furnace at Montezuma was to be turned loose to-day. Supt. Griswold says that it is not intended to be made much more than a trial run—the only matter being that if the success is made expected of it, there will be no need of putting up a different or larger water-jacket. In these matters, the events of the next week or two will cut no unimportant figure in the immediate future welfare of this county.

FROM SOUTHERN MONO.—Frank Alman dropped in today, having arrived last night from Benton on a business trip here. He says that the town of Benton is quiet as usual in business matters. The Dunn mill, which is being run by John Milliner, is being fitted up with a new battery for working ores for the Wild Rose mine. The Wild Rose is situated in Clover district, and belongs to Archie Farrington, formerly of Candelaria, and is spoken of as being a fine property. The mine, above the water level, will yield sufficient $75 ore to keep the mill going. The railroad grade has been completed over the summit, and to within 3 or 4 miles of Benton, its nearest point to that place. The track is now laid to McBride's. In Clover district, Joe McDermott's new 5-stamp gold mill has been running steadily since October 20th on ora worth about $40 per ton, working 9 tons per day. The dump at the mine—the Banner—contains some 600 tons ore already out, and "plenty more in sight."

MINING TRANSFERS.—Deeds transferring mining properties as follows have been placed in the county records during the week: Wm. B. Robertson to R. Gleon and J. W. Murphy, mineral spring in Coso mountains, $1 consideration; Daniel Probst and Jos. Hanger to E. H. Edwards, 750 ft in Mountain Sheep, Enterprise and other mines situated in Beveridge district, for $500.

AN INTEREST SOLD.—It is stated that during their visit last week to Bishop Creek, Messrs. James Crossman and John Wheeler, tha well-known mining men, purchased a one-half interest in the Sacramento gold mine. The ledge has been opened 100 ft deep, and, judging from the amount of gold already taken from it by the arastra process, it must be a good property.

MARIPOSA.

THE COMPROMISE.—Mariposa *Gazette*, Nov. 25: This mine has opened out in the lower levels quartz of a high grade, and they are now busy milling it, and realizing profitable returns. A new line of heavier pipe is being substituted from the reservoir to the works.

BANDERETA TUNNEL.—At the 1330-ft point a large vein of ore came in, showing a fissure from 6 to 8 ft wide, and well-defined walls. The quartz taken out shows well with free gold, and prospects well. Sufficient is being taken out to keep the mill employed, and is estimated to pay not less than $25 per ton. The tuanel is to be pushed ahead another 100 ft, with a view to tapping the main vein of the famous Banderita mine. The prospects of the Banderita are very encouraging.

THE TUNNEL & DICKINSON.—This mine, three-fourths of a mile below the Banderita, has about 00 tons of $40 rock on the dump ready to crush. Billy and Charley are both pushing ahead the work on the arastra flume and dam to completion, and in a short time all will be in operation.

THE DILTZ.—We visited this mine last Wednesday, where we found Captain Diltz. Upon our arrival, the Captain suspended work, and led us to a portion of this mine we never had visited before. It stands at the head of a string of sluices, which is made available whenever there is water sufficient to wash the heavy embankment of gold-bearing dirt.

THE SCHRODER.—This mine, which is but a short distance from the Diltz mine, has been sufficiently exposed and developed within the past two years by Mr. Schroder to show most conclusively that he has a mine that will compare favorably with the Diltz or other first-class mines of the State.

MONO.

ON FULL TIME.—*Free Press*, Nov 25: This evening the Syndicate mill will be started up on full time. For several months the stamps have been kept running but 12 hours a day, or about half time. The mine is looking well, a new ore proposition having been developed during the past two weeks. The superintendent is of the opinion that the new ledge will keep the mill supplied with ore for at least a year. This is a bit of good news.

NEVADA.

O'CONNOR MINE.—Grass Valley *Union*, Nov. 24: The mill at the O'Connor mine has commenced running on rock taken from the 180-ft level and stopes of tha mine. This rock is mostly of good quality, showing well in free gold and sulphurets. The vein is between 3 and 4 ft in width. It is the intention to make a crushing of 100 loads before Thanksgiving. The rock now being crushed is a great improvement upon that crushed several months ago, from which an indifferent result was obtained.

A GOOD PROPERTY.—The Morning Star mine, near Ophir, Placer county, promises to develop into a fine property. It is owned by Hawkins and Perrdons, who have been working it for about four years. The shaft is now down about 260 ft, and the ledge in the bottom looks very fine. The last crushing yielded 3¾ ounces of gold to the ton. A new hoisting engine, built by M. C. Taylor, of this place, will soon be put up, which will enable the owners to sink to a great depth. A new shaft is also being sunk 150 ft north of the main works, in which the ledge is 4 ft wide and the rock will pay $18 75 to the ton.

EAST EUREKA.—*Foothill Tidings*, Nov. 24: The East Eureka, or O'Connor, as it was originally called, has struck some good ore in their No. 2 level. The ledge in the stopes is something over 4 ft in width, and the ore looks to be considerably better than the average milling ore. The 20-stamp mill started up on Monday last. Everybody who is familiar with the past history of the East Eureka speaks in the most flattering terms about the mine.

THE MENLO.—This property will soon be sold to pay off an indebtedness of $7,000. There must certainly be something wrong with the management of this company in the East, as affairs out here have been conducted in the most economical manner possible. Hoisting works have been placed on the property, old shafts and tunnels cleared out, and everything along the line of the property placed in a condition for working and developing the numerous ledges embraced in the consolidation. Then came the financial difficulties with Bothwell, Clark & Co., who are the principal owners in the Menlo, and in consequence thereof all operations were closed down. The Menlo property is just now in shape to be profitably worked, and just at this juncture it is a matter of regret that affairs with Bothwell, Clark & Co. were such that work had to cease on the mines. The consolidation of the Menlo embraces numerous well defined quartz veins, several of which have yielded ample bullion to justify a good expenditure of coin in searching for their treasure chambers, and the manner in which Mr. Joseph Snyder, the superintendent of the property, proposed to develop these mines was the most practical and economical of any which has ever been proposed. By the shaft and tunnel, started by the Menlo, three or four ledges that are known to exist could have been reached and good milling ore extracted from them at a very small cost. We see no reason why this work should not be kept going, because the property is just in a condition now that good results might reasonably be expected from any futher work. The total expenditure on all the Menlo property, including fixing old shafts and drifts, running the tunnels and building the hoisting works, has been but $72,000; this also includes the $7,000 indebtedness now on the property.

IDAHO.—The Idaho is rapidly opening up the 14 level, and indications are very favorable for the development of a large and valuable ore body. The ledge in the 13 is considerably improved of late.

EMPIRE.—The Empire is looking as well, if not better, than it has ever looked. The lower levels are showing up splendidly.

IMPERIAL.—The Imperial is putting up a mill, and it will be driven by water power. Great hopes are entertained for this bright little prospect.

GRAY HOUND.—The Gray Hound is still driving its tunnel on the ledge. Considerable quartz of good quality has been taken out, and before long a crushing will be made.

NEW YORK HILL.—This mine is looking well in the north drift of the 13 level. This drift is up near the Rocky Bar, and is the place where the New York Hill expects to develop a good paying ledge. The ground is still very hard.

CON. LONE TREE.—The Consolidated Lone Tree quartz mining property is situated at Forest Springs, and the location embraces something over 4,000 ft. There are three separate and distinct ledges on the property, two of them having an average thickness of 8 inches, and the other a good 2½ ft. There is 700 ft of tunnel run, and the tunnel cuts all three of these ledges. There are also several shafts sunk on the property, all of them on a ledge, and some pan washings from one of the ledges yielded $8 and $15 to the pan. The matter panned was decomposed quartz, and many large lumps of gold were found among it. This property is in a fine timber region, and the mine is in good condition to work. With machinery on this property, it is the opinion of miners that it would be a paying institution.

A POCKET.—A party of prospectors, so we are informed, struck a pocket on Dead Man's Flat last week, and took out several pans which yielded $48 to the pan.

HARTERY.—The Hartery started drifting yesterday. The shaft is down 600 ft, and the ledge in the bottom is from 18 to 20 inches in thickness and looks well.

PLACER.

POSTPONED.—Placer *Times*, Nov. 26: The North Star M. Co. have posted notices asking for bids for running an incline tunnel into their mine for the purpose of prospecting the gravel, with a view to working the claim by drifting. Their claim is at the lower end of town, facing into the Dutch Flat canyon. They will start near the bottom of the canyon, and run in a westerly direction, with a pitch of 30 degrees, until bedrock is reached. That part of this hill has never been prospected.

PLUMAS.

TAYLOR PLUMAS MINE.—Greenville *Bulletin*, Nov. 20: All the machinery for the mill is now about ready for setting up. Teams are delivering lumber for the erection of the buildings, and millwrights and carpenters began work this morning. The weather is now very favorable, the roads are good, and these opportunities ought to be improved to the utmost. There is not a moment to lose, for should storms set in at this season, we know well enough what would ensue. The chances are, however, that there will be a few weeks of good weather, but no dependence can be placed upon this. The utmost must be done during every hour if the buildings are to be finished. In the mine work is pushed ahead steadily. The main tunnel is advancing on the ledge, accomplishing the double purpose of storing up ore for the mill and opening up new ground for stoping. The upper drift is also advancing well, and an opening will soon be made to the surface in the upraise. This will be of great benefit in airing the mine. There is no material change to note in the character of ore taken out.

CRESCENT MINE.—Repairs on the mill are completed. The water pipe was all laid on Monday, and it was the intention to start up the mill this morning, though we have not heard if this has been done. The ledge is now opened 180 ft in length, and the ore is still found to maintain the same high grade. All the storage room is filled with rock, ready for milling. The drain tunnel is being required very rapidly. Men are at work on both ends, and only about 150 ft remain to finish. This can be done in about 50 days; then the shaft will be pumped out and ore raised through it. This can be done almost from the start, as the ledge can be easily reached from almost any point in the shaft. The whole work is progressing very favorably.

CHEROKEE.—The pumps were started up at the Cherokee mine on Sunday, and will be kept running until it will be determined by the company what shall be done. At present nothing is known here about what course will be pursued, but some course will be determined upon soon. It is said that an agent of the company is coming here from New York to examine into the condition of the mine. If this be so, future action will be determined by his report.

TUOLUMNE.

THE FROZEN TRUTH.—*Independent*, Nov. 26: Mr. John App is running the App mine at Quartz Mountain, and is making it pay well. The first run yielded $14,20 per ton. The second run, on talc, produced $7.15 per ton. One man can get out about four tons per day of this material. They have 160 tons of this out, and expected to commence grinding last Monday. There are many mines in this county, if managed economically by practical men, would give good returns, but which now have a "black eye" by having been managed by fancy superintendents at princely salaries. It takes pretty rich rock to maintain a fast manager with fast horses and fast women, with whisky, cigars and private medicine charged to their company as "sundries."

NEVADA.

WASHOE DISTRICT.

CON. VIRGINIA.—*Enterprise*, Nov. 25: The joint California southeast drift on the 2700 level has been extended 21 ft.

SIERRA NEVADA.—West crosscut No. 1 on the 2700 level has been extended 34 ft, and the east crosscut 18 ft.

MEXICAN.—The joint Ophir winze below the 2900 level has been sunk 5 ft. The northwest drift on the same level has been extended 20 ft.

CALIFORNIA.—The joint Con. Virginia southeast drift on the 2700 level has been advanced 21 ft. Are still extracting ore from the croppings.

UNION CONSOLIDATED.—No. 1 winze on the 2600 level has been sunk 17 ft. The south drift on the 2900 level has been advanced 27 ft. During the week 53 tons and 200 pounds of ore have been extracted from the 2700 level.

OPHIR.—The joint Mexican winze below the 2900 level has been sunk 8 ft, and the main south lateral drift was advanced 21 ft. Are putting on new gears and making general repairs to the pumping machinery.

CHOLLAR.—The drift south on the 2600 level has been advanced 64 ft during the past week, making the total length of drift 320 ft. The material passed through has been porphyry, and quite free from water. The quantity of water flowing from the drift is steadily decreasing.

YELLOW JACKET.—There has been no change in the water in the mine since the last weekly report, it being stationary at a point about 1,150 ft above the 3000 level station. At the Wiutsrs shaft were employed sinking a winze in the old stope on the sagebrush level. Will have about 25 ft to sink to reach the 280 level of the old mine. The ground is much broken, and there is already quite a current of air passing towards the north shaft. Are extracting and shipping about 40 tons of ore daily. On the 21st instant we shipped three bars of bullion of the value of $8,075.

DIAMOND DISTRICT.

CUMBERLAND AND MAMMOTH.—Eureka *Sentinel*, Nov. 25: We learn from J. F. Morrison, an old miner, who has been at work in this camp and the neighborhood since 1869, some interesting facts about the Cumberland and Mammoth mines in Diamond district, about 18 miles north of Eureka, which mines are the property of the Enterprise Company, composed of San Francisco capitalists, who are represented here by E. E. Phillipps. The Mammoth is developed by a tunnel upwards of 300 ft in length, and by an incline between 50 and 60 ft deep. The tunnel has been run in upon the ledge, which varies in width from 2 to 12 ft. The ore is of a quartz character, but heavy in lead, of which it carries in the neighborhood of 60 per cent. The Cumberland, which has been developed to about the same extent as the Mammoth, shows a ledge of from 2 to 2½ ft wide, the ore being about 20 per cent. lead. The two mines are 3,300 ft apart. The ore in the two mines is of low grade, averaging $30, though some of it goes $60 per ton. We are told that it can be reduced at a cost of less than $15 per ton, on account of the great abundance of wood and water at hand. If this calculation is correct, and the promised quantity of ore holds out, the Enterprise Company has a valuable property. There are some 150 tons of ore on the Mammoth dump. Seventeen thousand dollars have been spent in developing the two mines since last fall, and the company, we are informed, have determined to erect furnaces next spring.

DOWNEYVILLE DISTRICT.

STARTED UP.—Grantsville *Bonanza*, Nov. 25: From M. Raphael we learn that the Downeyville furnace started up again last Wednesday, under the management of Mr. White, a gentleman of large and varied experience in the reduction of ores. The mine is looking splendid, and producing an abundance of good ore. Below the water level in the silver cave the character of the ore has changed to a very fine galena, which is becoming so hard that it requires blasting. Undoubtedly this is one of the most valuable mining properties in the State, for as work progresses it continues to open out bigger, and has every indication of proving a permanent mine. Downeyville is destined to be one of the leading mining centers of the Pacific slope. There are several prospects in this district that only require a judicious outlay of capital to develop into valuable mines.

ESMERALDA DISTRICT.

STARTED UP.—Esmeralda *Herald*, Nov. 25: The Cortez mine started up Thursday with a good force of men. Superintendent McIntosh informs us that as soon as he can get the men he will have about 40 at work in the mine.

THE MILL.—Thursday we visited the mill at Gregory Flat, in company with A. W. Bronn, of Mason Valley. We found Mr. Barton busy at work, and the machinery nearly all in place. The engine and boiler are set, and the battery and stamps are in place. All of the grading is done, and most of the timbers for the building are framed. The mill will be ready to operate by the 10th of next month.

EUREKA DISTRICT.

EUREKA TUNNEL.—*Sentinel*, Nov. 22: Everything looks well in and about the Eureka Tunnel mine. The foul air has been replaced and made fresh by the blower which operates at the mouth of the tunnel. The second level, 108 ft below this tunnel level, is about 160 ft in length, and runs east and west. In a south drift from this a fine body of carbonate ore is uncovered. At the end of this drift a winze has been sunk about 20 ft, at the bottom of which the ore has an average thickness of 2 ft, and seems to be going down strong at an angle of five degrees in good, clean ore, requiring no assorting, and evidently of the same rich quality now being taken from other parts of the mine. In the north drift of upraise from this level ore has been followed and extracted of a uniform grade of 100 ounces to the ton for a distance of 120 ft, and still continues, the vein varying in width from 6 inches to 3 ft. In the east stope from this drift there is a good body of high-grade ore of the same varying width. This stope is now yielding from 2 to 3 tons of ore per day. The general output of the mine is 8 tons, with prospects of an increase. The last batch of ore—60 tons—taken out of the mine without assortment, assayed at the reduction works of the Eureka Con., $135 per ton, the net return of which will be about $100 per ton. There are 25 men employed in the mine.

GILLIS MOUNTAIN DISTRICT.

DEVELOPMENTS.—Cor. Virginia *Enterprise*, Nov 24: With pleasure I again note developments in the mines of Camp Middlesex. Yellow Jacket, owned by Messrs. Ogg, Jamieson, and one-third interest to the estate of the late Thomas Taylor, is showing a marked improvement both in quantity and quality of ore. A double force of laborers is now employed, equally divided in sinking and tramping ore. The incline shaft following the vein is now down to the depth of 60 ft. The most approved method in sinking is to keep the vein under foot by excavating the upper strata for 6 or 8 ft at intervals, when the laborers go back and take up the "floor vein," which averages from 6 to 12 inches in thickness, of "black metal," assaying from $100 to $3,000 per ton. The varied formations of this mine are an interesting and instructive study for the geological miner.

SOUTH MOUNTAIN.—This mine, owned by J. B. Benton and Kenedy Brothers, is a strong vein of even and high-grade ore. Much labor has been expended on the mine, and a large quantity of ore is now exposed to view.

MIDDLESEX.—This mine has just completed a shipment of ore, to be "toted" across the continent and around the world, for the exclusive benefit of "railroad and steamship companies, ore shavers and foreign reduction works, including." This mine is a property of much merit. The vein is clear and well defined (almost a free milling proposition), rapidly improving in strength and richness as depth is attained.

CREDITOR.—This mine will soon come to the front and speak on merit. Wheeler, Tremont, Central, Opportune, Treasury, Highland, Bay State and Empire Wave, ditto.

ILLINOIS COPPER.—This mine, owned by Messrs. Furlong, Baker, White and Dunn, is situated three miles easterly from our camp. The mine shows by general characteristics of formation unmistakable proof of its not being a mere prospect, but a real mine—a copper property second to none in this portion of Nevada's mineralized land. As the work of development progresses, large bays of metal are certain to be encountered. Less than 100 ft of incline shafts and drifts have thus far been made on the mine, and by careful approximation there is at least from $20,000 to $25,000 worth of ore on dump and in the mine exposed to view. This ore is mostly of high grade, assaying from 40 to 60 per cent.

LEWIS DISTRICT.

BETTY O'NEAL MINE.—Lewis *Herald*, Nov. 22: There has been no work done underground as yet the past week, except pumping. The water is now about half way below the top of the station, and will be out in a few days. The building is almost completed, and is much roomier and better arranged than the old one.

MORNING STAR.—North drift, third level, is in 135 ft; advanced during the week 8 ft. This drift has been much broken for the last two weeks, but is now in good ore. The raise has been started from head of incline to surface, and is up 5 ft, in 4½ ft of high-grade ore. The south drift, third level, is in 3½ ft of fair-grade ore of a very hard character.

MOUNT CORY DISTRICT.

A BONANZA.—Esmeralda *Herald*, Nov. 25: Reports from the Mount Cory mine are of the most flattering character. Parties in from that district inform us that the Mount Cory is a second Northern Belle. The deeper they go the better is the showing. They now have developed a ledge 140 ft in width that will average $40 per ton. Two ft of this will run as high as $1,000 per ton. From all reports, the Mount Cory is the biggest mine on the coast.

MOUNT ROSE DISTRICT.

MILL.—Lewis *Herald*, Nov. 22: Messrs. Sadorus and Cope are putting up the Red Stone mill, which will be completed in one month's time, and will be of 12-horse power. The ore is gold rock, of which there has been some exceedingly high-grade ore found. Mr. Cope is an old resident of Lander county, and we hope he has a large bonanza.

PYRAMID DISTRICT.

PROSPECTING.—Reno *Gazette*, Nov. 25: The Roma-Union tunnel is now in 850 ft, and making good progress daily. W. R. Chamberlain has men employed doing assessment work. He has faith in the final prosperity of the district, and will continue to stand by it. John Armstrong is having work done on his claims, and the Buckeye Company is doing assessment work. Considerable prospecting is also being done in the vicinity. Pyramid will come to the front some day. It can show more ore on the surface than any other district on the coast.

SAFFORD DISTRICT.

IMPORTANT MINING SALE.—Eureka *Sentinel*, Nov. 25: A half interest in the Onondaga mine, at Safford, was disposed of yesterday to Chicago capitalists, represented here by E. L. Bennett. The vendor is B. C. Safford, the oldest-time prospector in eastern Nevada. The remaining half of this mine is owned by George O'Briter and the estate of Dr. Hubbard of California. The consideration, we understand, is $50,000, a part of which has been paid in cash to fix the sale. The Onondaga is considered a first-rate property, and the best in the district. The ore it yields is free and mostly sulphureta. A force of men will be put on immediately to extract ore, and a mill will be put up without delay on the Humboldt river at Oerald Station to reduce it.

ARIZONA.

CENTRAL ARIZONA.—Tombstone *Republican*, Nov. 25: It is with pleasure the *Republican* announces that Central Arizona (the old Vulture) was worked to a profit for the month of October. The official statement from the home office in New York is: Gross product, 1,328 ounces bullion, valued at $21,505.58. Ore and waste crushed, 0,498 tons; average product per ton, milled, $3.31. Net product, $4,198.10. From this time forward this mine may be looked upon to yield its stockholders a margin of profit. The waste caused by the great cave must now be nearly worked out, and they will enter upon the large bodies of $8 and $10 ore that is known to exist in the mine. There are now, no doubt, a series of prosperous years before the company.

CASTLE CREEK.—Arizona *Gazette*, Nov. 23: J. M. Schriver returned Monday from his Castle Creek mines. His reports times booming. He is now sinking two shafts, one on the Jackson and the other on the Kentucky lode, about 100 ft apart. When a depth of 100 ft is reached he proposes running a level connecting the two. With every additional foot the lead grows better, and is now 4 ft wide. W. C. Collier is running three shifts on his work, and it is reported that his company will shortly put in a smelter. Castle Creek is the Clifton of central and northern Arizona.

COLORADO.

THE DIAMOND TUNNEL.—Georgetown *Courier*, Nov. 23: The Diamond tunnel has at last intersected the Corry City lode, which it has been steadily approaching for many years. The first indications of the lode appeared in the roof of the heading on the 10th, and by Saturday the heading was squared up in the crevice rock, its total length being 2,101½ ft, and on the dip of the lode its depth is estimated at 1500 ft. On Monday a contract was let to drive the tunnel across the lode, and after that has been done an estimate can be made in regard to its value. At the surface Carpenter & Ballard, lessees, have been engaged at cleaning the shaft out, which they find has been sunk 90 ft below the cross-cut level, and 150 ft from the surface. At the bottom they have found a vein of mixed ore 5 ft wide, a sample of which, taken from the whole width of the vein, assayed 137 ounces per ton. The lessees have put a pump in and expect to commence drifting and stoping. On the No. 8 lode a contract has just been let to raise and drift 50 ft, the vein of mixed and solid ore at this point being 3 ft wide, a mill-run of which returned as follows: First class, 54 ounces, 30 per cent. lead; second class, 30 ounces, 20 per cent.; third class, 20 ounces and 16 per cent.

IDAHO.

SMELTERS.—Ketchum *Keystone*, Nov. 17: The smelters have been delayed somewhat during the past 10 or 12 days by slight breakages in the machinery, to duplicate which it was necessary to send to Muldoon. At present everything is running as smoothly as usual.

MILL.—Captain Henry Guyer, well known hereabouts as having been the successful operator of the Custer quartz mill, located at Custer, Idaho, and the Philadelphia smelter in this place, has been engaged by the Vienna Company to start into operation and manage their immense mill at Vienna. The process is precisely that of the Custer mill, and inasmuch as the Captain will be at home, the company has nothing to fear in the way of a successful operator.

SQUAW CREEK.—Idaho *World*, Nov. 21: The prospectors in Squaw Creek district are quietly digging away, developing their prospects. Fourteen or fifteen men are at work near the Liberty mine. A fine looking ledge was discovered the other day about three-quarters of a mile north of the Liberty. Five men went to work the other day on it. They are sinking a shaft. Two men commenced work a short time ago on a shaft at the Liberty.

MONTANA.

MONTANA COPPER COMPANY.—*Inter-Mountain*, Nov. 22: To any one who will take the trouble to visit the smelting works of the Montana Copper Co., the enterprise and success of that wealthy corporation will become at once apparent. Six matting furnaces are now in operation, whose product is to be still further increased by the erection of two calcining furnaces, which are now being constructed. The matting furnaces, it seems, are capable of reducing more ore than the calciners in present use can desulpburize, and the additions are being made in order to increase the matte product. The company is now in good shape for the winter's run. At least 10,000 cords of wood are already stacked up at the works, and it is estimated that the company owns 15,000 cords in the timber, in addition to which immense bins of coal, containing probably 1,000 tons, are on hand at the smelter. Some of the furnaces use wood and some consume coal. All of them are not yet provided with coal grates, and it is doubtful whether they will be, as coal at $8 per ton is not much cheaper than wood at the ruling price. The mine is said to be in excellent shape, and could easily increase its present ore product to 200 tons per diem, if the capacity of the reduction works were sufficient to justify the increase in the working force. On the 200 level the vein is as rich, regular and extensive as ever, and contains considerable silver, which, however, is of no value, as, when smelted with the copper, it becomes inseparable except by a very expensive process. Thousands of dollars in silver are thus wasted—more, in fact, than a number of our promines silver mines are producing. The Montana Company is working about 150 men, of whom 75 are employed in and about the smelter and the remainder in the mine. Under the management of Mr. Pouto, the affairs of the company are ably conducted, and the matte product averages between 15 and 18 tons daily. From 10 to 20 tons of crude copper are also shipped daily.

UTAH.

DETROIT DISTRICT.—Salt Lake *Tribune*, Nov. 24: This camp is receiving considerable attention from railroad officials, four having visited it within a short time, and all have expressed astonishment at the extent and richness of our mineral belt of copper ores. What surprises them most is to see one pound of metallic copper run out of two pounds of ore in a blacksmith's forge.....The Desert G. & S. M. Co., at a depth of 155 ft., have crosscut some 30 ft of ore in one direction. How wide the ledge is has not yet been determined. The crosscut shows one 18 inch streak of green carbonate, assaying 55 per cent copper. They have a large body of red oxide of copper.....Among the old miners located here is Mr. Jacob T. Miller, the original discoverer and part owner of the celebrated Miller mine, in American Fork, which has turned out over $1,000,000. Mr. Miller has a number of very fine locations here.

ALTA.—Salt Lake *Tribune*, Nov. 25: The mine owners at Alta, Little Cottonwood, rejoice in the unprecedented favorable weather, which enables them to transport their ores as in summer time. In former years the roads were usually blockaded with snow early in November, but now they are clear.

The Denver Exposition—No. 15.

[Editorial Correspondence.]

North of Wyoming, and reaching up to the British possessions, lies the magnificent Territory of Montana, which, as well as Wyoming, offers great inducements to emigrants, whether for mining or agricultnre.

The Mineral Resources of Montene,

Although as yet but imperfectly explored, are known to be very extensive and rich. Besides the precious metals, iron, coal, copper, cinnabar, etc., are also abundant. Her mountains are veritable store-houses of mineral riches, only waiting the magic touch of capital to bring them forth. This Territory has already added not less than

One Hundred and Fifty Millions,

Of dollars in gold and silver to the currency and bullion of the world. Since 1864 the annual yield has varied from $5,000,000 to $8,000,000. Alder Gulch alone, in Madison county, a ravine near the extreme southwest corner of the Territory, and in which Virginia City is also located, has contributed about $40,000,000 of the aggregate yield, and is still yielding over half a million per year. Active mining operations are carried on in 10 out of the 12 different counties into which the territory is divided. The Rocky mountain divide forms the western boundary of the Territory, and it is along the eastern slope of these mountains, with a northwesterly and southeasterly trend for about 300 miles, that the principal mines in the territory are found.

Butte City, the Principal Mining Center

Of Montana, is about 50 miles northwesterly from Virginia City, and is the present northerly terminus of the Utah and Northern branch of the Union Pacific. The mines about Butte City produce nearly one-half of all the gold obtained in the Territory, and there can be no mistake about the value of the developed mines in any portion of Montana. A large and prosperous city has grown up at Butte, and it was from this locality that nearly all the exhibits in the Montana display at the Denver Exposition were sent. The bullion yield of Montana is nearly equally divided in value between gold and silver.

The silver ores consist principally of sulphurets, although a great proportion of rich chlorides is also met with; occasionally native and wire silver. Specimens of both gold and silver were shown.

In addition to these, Butte also furnished some wonderfully rich specimens of copper ore, from properties which have quite recently been developed. The Liquidation, which exhibited some very rich ore, is regarded by some as the richest copper mine in the Rocky mountains. It has already developed a productive capacity sufficient to feed continuously a 50-ton smelter. At the bottom of the shaft (200 feet deep) the vein is about 50 feet wide. The mine recently had upon its dump 1,000 tons of 20% ore, 3,000 tons of 15% ore, and 100 tons of 40% ore, which has since been sold to a Montana smelter. The Lexington mine, owned by a French company, and also located at Butte City, has a 50 stamp dry-crushing mill (850 pound stamps), with 20 pans, 10 settlers, two agitators, and two Stedefeldt roasting furnaces.

The First Gold Quartz Discoveries

In this Territory were made in Bannock, until recently the county seat of Beaver Head county. One of the most important mining enterprises in this county is that at Glendale. The company's reduction works are at Trapper Creek, 10 miles distant from the mines, where they have an extensive water power and two water-jacket furnaces, with all needful auxiliaries. Besides the large amount of first-class ore constantly on the dump, they have a reserve of at least 50,000 second-class ore waiting to be concentrated. The output for the first six months of 1881 were 240,000 ozs. of fine silver, 900 tons of lead and about 50 tons of copper.

At Park City, in Lewis and Clark county, is the famous Whitlach-Union mine, out of which an aggregate of over four and a half millions of gold have been taken.

Silver Bow county is the smallest in area in the Territory, but it possesses many valuable mines, among which we may mention the Alice, which is capitalized at $10,000,000. The company also own two other mines near by. The aggregate product of the three for 1881 was something over $1,000,000. The company is known as the Alice gold and silver mining company. It paid $400,000 in dividends during the 10 months from March 1, 1881. Its gross product since October, 1879, has been over two and a quarter millions. There are many other very valuable mines in various portions of the Territory, which are, perhaps, equally as worthy of mention as the above, but we have no space for further particulars. Suffice it to say, that the mines of Montana will, for an indefinite period of time, continue to add their regular annual quotas of wealth to the bullion product of the nation.

Placer Mines.

Next to California, Montana probably has the most extensive system of placer mines of any State or Territory in the Union. The first discovery of gold in Montana was in the placers of Deer Lodge county, from which about twelve millions have been taken from some 3,000 acres of placers, worked to an average depth of 15 feet. The ditches now in use in this county aggregate a length of 110 miles, carrying about 10,000 inches of water. The indications are that the placers of this county will afford profitable work for many years to come.

The large amount of nearly forty millions taken from Alder Gulch was almost entirely placer gold, and the mines there are still paying largely. Three hundred thousand dollars in placer gold from this gulch was last year purchased by two banks, and yet the season was a very unfavorable one by reason of the short supply of water. It is estimated that at one time fully 30,000 people were interested in the development and working of this gulch. Nearly $3,000,000 have been taken from the placers of Beaver Head county.

The placers of Lewis and Clark county have produced not less than $8,000,000 since 1864. Many of the placers of this and other counties throughout the Territory are now lying idle, under the operation of the new mining law, which enables a few persons to obtain patents for large mineral tracts which under the old law would be worked at the present time by prospectors or small companies.

Meagher county also contains many valuable placer mines, which have been worked more or less since 1866, and which still continue to yield largely. The present annual yield of the placers of the four counties named is about $1,250,000. There is more or less placer mining carried on in other parts of the Territory, and under a more favorable mining law the annual yield would no doubt be greatly increased. The cost of transportation is so great at present that parties holding large extents of mining ground prefer waiting until the completion of the railroad system for the Territory will enable them to construct flumes, ditches, etc., at cheaper rates. The same improvements, by reducing the cost of living, will also cheapen the cost of labor.

Mills and Reduction Works.

We have only an imperfect record of the mills and reduction works in the Territory. So far as we have them, they are as follows:

County.	Mills.	Stamps.
Beaver	2	11
Deer Lodge	1	20
Jefferson	3	30
Lewis and Clark	7	171
Madison	5	85
Meagher	1	15
Silver Bow	14	390
Total	33	722

We have not included in the above table for Lewis and Clark county the mill and stamps of the famous Whitlach-Union mill, for the reason that we have not the figures before us at the present writing. There is also a single-stamp steam mill in that county not enumerated above, but which is reported as doing the work of an ordinary 5-stamp mill.

Furnaces.

There are four furnace plants in Silver Bow county with an aggregate capacity for treating 200 tons of ore per day. We have also before us a report of two furnaces in Jefferson county, with a capacity of 30 tons each, and another just completed; also one each in Gallatin and Meagher counties, the latter with a capacity of 20 tons. We have reason to believe that the above record is not full.

The Agricultural Resources

Of Montana must not be overlooked. She possesses immense areas of the finest pasture lands, now trodden only by the hoof of the buffalo, deer and antelope, but which, in the near future, will be made to support vast herds of horned stock, horses and sheep. She also possesses numerous large and fertile valleys, where wheat, oats, rye, and all the hardy vegetables and fruits may be produced in abundance. Of her 90,000,000 acres of area, only 20,000,000 are classed as mountainous. Two of the largest rivers on the continent rise within and flow through the entire length of her territory. The Yellowstone lies wholly within the Territory, and is navigable for 450 miles. The Missouri flows for over 1,000 miles on Montana soil, affording a large extent of navigable waters. One or two other smaller streams in the Territory are also navigable. Almost every square mile of the Territory is drained or watered by these noble rivers and their hundreds of tributaries. Indeed, Montana can boast of the finest river and valley system of any State or Territory in the Union.

In addition to her water-ways, a railway system has been laid out, and is in rapid process of construction, embracing some 2,000 miles or more of track, and by which, inside of two years, 11 out of the 12 counties in the Territory will be entered by the iron track. There is room for millions within the limits of the magnificent Territory of Montana. Mr. J. B. Read, the Commissioner in charge of Montana's interests at the exhibition, won for himself the goodwill and esteem of all who became in any way acquainted with him. W. B. Ewer.

Wilcox is a little town on the Southern Pacific railroad, about 80 miles southeast of Tucson. Many of the maps do not name it, for it is but two years old. It is to the side of the center of Sulphur Springs valley. It is the shipping station of the Globe district copper and the receiving station of freight for Globe district; also for Camp Thomas, San Carlos reservation and Camp Grant. Large shipments of coke arrive here for Globe, and large Government orders of goods for San Carlos, to be given to the Indians.

Cost of Mining in Sweden.

We take the following items from a report by Prof. R. Ackerman, translated in *Iron*.

Miners in Sweden are generally paid by piece-work, at some places according to the quantity of rock broken out, but mostly according to the length of hole bored, and sometimes these two methods of payment are combined, and the workmen then paid for the length of hole bored by each. If day wages are paid, the miners receive from 1s. 6d. to 2s. 6d. per day; but in addition to this, they have many advantages, such as free dwelling-house, fuel, potato land, fodder for a cow, etc., so that it is difficult to give the exact amount of their earnings. Single-handed or "one man's boring" is now general, but at some places the so-called "two men's boring" is still in use. The bore-holes have a diameter of from eight to nine lines, and the cost for downward boring, "under hand," is from 2½d. to 6d. per foot, according as the workmen, besides wages, have more or less emoluments, but for boring upwards, "overhand"—"dry boring"—often twice as much. Steel is now exclusively used for hammers and boring tools, and the most common explosives used are mining powder—both in round grains and in the form of cartridges—and dynamite, as well as others mixed with nitro-glycerine, as, for instance, sebastine. In consequence of the numerous accidents, the use of nitro-glycerine in its pure form was strictly prohibited some years ago; but as this prohibition has of late been relaxed, its use is again frequent. The work a miner is capable of performing naturally varies according to the hardness of the gangue, his own skill, and the explosives employed, but the following figures may be quoted as an approximate average: Per day and per man it is commonly 5 to 8 ft. downwards, sometimes even 10 to 12 ft., but with boring upwards only half as much; and per month a workman may break as much as 50 tons of rock, whilst the quantity of explosives used of the more powerful kind is one pound to 1 to 2 cwt. of rock, or, if mining powder, 40 to 60 cwt. The cost of the dressed ore on the bank amounts to from 9 to 35 öre per cwt., or 2s. 6d. to 8s. 10d. per ton.

The winning of the ore is generally carried on by sinking shafts, driving levels, and underhand stoping, in such a manner that, when a shaft has been excavated through the loose layer of earth, and so deep into the bed of the ore itself that the part of the solid rock which has been bored through is considered to afford a secure roof, levels are laid out in the direction of the strike, and whilst thus the main sinking or shaft opened from the outset is continued steadily downward, the ore is taken out by underhand stoping, the necessary supports being left for the walls of the mine. The space in the mine from which ore has been removed is thus, in general, left open or unfilled, and it is only in some of the iron mines, whose sides, in consequence of cracks and loose places, cannot be kept up by supports, that close timbering must be resorted to; still, of late years, the vacant spaces have in some mines been refilled with barren rocks, and the ores then taken out by overhand stoping. At most Swedish mines the latter method of working is certainly unnecessary, but it is probable that in future it will be oftener used, as many mines have, with the other method of working, become insecure. On the other hand, the want of sterile rock for filling the vacant space will prevent its adoption at several mining fields, as nearly half as much is required for this purpose as the entire mass of rock broken out. When the shaft is perpendicular the ore is taken out of the mine in barrels (kibbles), either made of wood and hooped with iron, or of Bessemer metal, which hold 6 to 8 cubic feet or from 9 to 15 cwt. of rock, and these are hoisted to the bank by wire ropes. When the shaft is inclined there are either employed so-called "slant ways," along which the ore is raised in barrels or railways, both following the slope of the shaft, and if a railway is constructed, the ore is, in that case, loaded into wagons ("dogs" or "bears") which hold from 15 to 22 cwt. of rock. For the horizontal conveyance of the ore to the place from where it is raised, wheel-barrows, and where the distance is short, hand-barrows have hitherto been mostly used, but now railways begin to be more employed in their place.

The ore is further, as a rule, reloaded at the shaft, and it is only when the hoisting is carried on with barrels, and a railway simultaneously employed for its conveyance from the working chamber to the shaft—as is, for instance, the case with overhand stoping—that the ore is raised to the bank without reloading. On the other hand, there is not found in any Swedish iron mine each an arrangement for raising several wagons simultaneously as is found in nearly every mine in England, and which is so necessary for raising any large quantity of ore at once. The cause of this is, in the first place, the way in which the mining is carried on in Sweden, by which it is but seldom possible to collect as much ore upon the same level as is required for this method of hoisting; and, secondly, by the difficulty of getting it raised to the hight required, where water-power is employed as motor for this purpose.

The raising of water in Sweden is generally effected by suction pumps, placed under each other, or by so-called "pump-settings," each of which has a length of 30 to 36 ft., but in deeper mines force-pumps, which are much more effective, are employed. At smaller mines the same power is sometimes employed for raising both ore and water, but generally different motors are used for these purposes. As Sweden abounds in streams, available water power is, as a rule, to be found in the neighborhood of mines, and to bring the water power to the mines there are employed so-called "konstgangar," consisting of wooden pipes joined together at the end, and in some cases also wire ropes. Such "konstgangar," which sometimes have a length of 10,000 ft., are very common for bringing the water power to the pumping stations, but they are seldom employed for raising the ore, steam being mostly employed for this purpose, especially where the distance between the mine and the nearest waterfall is too great to allow of the use of wire ropes.

In the year 1880 there were 193 steam engines in use in the Swedish iron industry, of which 83 were employed in the iron mines, but most of these were only of 10 to 16 horse power.

If the period of prosperity for the Swedish iron manufacture, which began in 1871 and ended in 1873, is excepted, the demand for Swedish ore has from year to year been in proportion to the supply, which has been met without difficulty, on a count of which, also, the price of iron ore before the period just mentioned was at most mines so low—20 to 30 öre per cwt. (5s. 2d. to 7s. 8d. per ton)—that the only object of the mine owner was to get up at the lowest possible cost, for the occasion, the exact quantity of ore necessary for the year's demand. Such a way of working a mine is, however, not compatible with a truly rational method; and it may further be a question whether such a method is at all possible in mines where, as is the case in many places in Sweden, the same deposit of ore, in a nearly vertical position, is worked, not by a single company, but is divided among several different owners, who each work in their respective holes, and are apt to come into collision with each other underground.

Although it is admitted that the arrangements and working at many of the Swedish mines are susceptible of improvement, it ought to be pointed out, on the other hand, that a greater part of the iron deposits in Sweden are too limited in extent, and the supply of ore too uncertain, to admit of any great outlay; and also that the existing state of things is, to a great extent, caused by defective arrangements in times gone by, which could not possibly be rectified without great difficulty and expense, and without the combined action of several very divergent interests. During the last five to ten years many modern improvements have, however, been introduced into the mining industry of Sweden; and there is no doubt that, had the high prices which Swedish ore fetched 10 years ago been maintained a little longer, mine owners would have borne any expense in order to increase and generally improve their production. In the year 1880, the last for which we possess statistics, 352 iron mines were worked in Sweden, from which were raised 755,000 tons of ore and in which were employed 5,008 persons, among whom 328 were women and children. There were 36 accidents, of which 18 were fatal.

New Foundry Enterprise.

The Pacific Iron Works, Rankin, Brayton & Co., of San Francisco, have recently concluded an arrangement with Messrs. Carlisle, Mason & Co., of the Excelsior Iron Works, of this city, for the construction of mining, milling and smelting machinery. The Pacific Iron Works have been in successful operation for more than 30 years, and have contributed perhaps more than any other to the many improvements in the manipulation of ores, which has made mining one of the great industries of the times. A large experience and a thorough practical knowledge of the treatment of ores, and the adaptation of machinery for this purpose, has made the Pacific Iron Works the foremost establishment of the kind in the country.

The works of Messrs. Mason & Co. are one of the pioneer establishments of Chicago, and the firm has long been recognized as one of the most successful and reliable in this part of the country, and give assurance that the same high standard of work will be maintained that has made the Pacific Iron Works so famous.

The combination referred to will attract much interest among mining men in all parts of the country, and afford an opportunity for Eastern purchasers to secure on this side of the continent all the improved appliances relating to mining machinery that have been developed on the Pacific coast during the past 30 years.

The office of the Chicago branch of the Pacific Iron Works is located at 182 Dearborn street, and is in charge of Mr. Willis G. Dodd, a gentleman of large practical experience in this line of work.

The New York office is located at 35 Broadway, and is in charge of H. B. Murray.—*Chicago Mining Review.*

Spain is to have a national mineral exhibition to consist of minerals, metals, pottery and glass. It will be opened by King Alfonzo on the 1st of April, next year, and will remain open to the end of June. The call for such an exhibition came from the Spanish press, and it is a sign of the times that Spain shows an anxiety to develop her industrial resources as much as possible. The plan for the exhibition was laid before the King in March last by Senor Jose Luis Albareda, the Minister of Commerce and Agriculture. Of late years mineralogical industry has been advancing in Spain with "giant strides."

Pacific Coast Lumber Interest.

Later announcements have been issued from the census bureau giving the statistics of forestry of the State of California and Oregon and of Washington Territory. With regard to California the bulletin says: The principal trees of the State are redwood, red fir, tide water spruce, chestnut and oak on the Coast Range, and sugar pine, yellow pine and red fir on the Sierra Nevada. Any estimate of the actual amount of lumber standing in the State, except redwood, is not possible with the existing knowledge of the country. The principal lumber industry is confined to the redwood belt, on the line of the Central Pacific Railroad on both slopes of the Sierra Nevada, to points in Butte, Tehama and Mono counties, and in the San Bernardino mountains. The total product of the State for the census year was 304,795,000 ft. of lumber, 242,400,000 laths, 138,718,000 shingles, 2,063,000 staves and 1,203,000 sets of barrel headings.

In Oregon the most valuable trees are in the order as set down; red fir, tide water, spruce, red cedar, hemlock, Port Orford cedar, white oak, sugar pine, chestnut, oak, larch and scrub pine. The principal lumber industry centers near Portland and Empire City. The product of the coast regions for the census year was 151,443,000 ft. of lumber, 17,950,000 laths and 2,745,000 shingles. The product of the State east of the Cascade Range was 25,798,000 ft. of lumber, 295,000 laths and 2,295,000 shingles.

Washington Territory, according to the bulletin, is covered west of the Cascade mountains by the heaviest belt of forest growth in the United States. The most valuable trees of this region are red and yellow fir (covering about seven-tenths of the forest growth), red cedar, hemlock and water tide spruce. East of the Cascade mountains the most valuable trees are red fir, yellow and white pine larch, red cedar and hemlock. The principal lumber region is confined to the shores of Puget Sound. The product of this region for the census year was 144,387,000 ft. of lumber, 6,550,000 laths, 710,000 shingles and 2,366,000 staves. The product of the coast outside of the Puget Sound region was 9,599,000 ft. of lumber and 200,000 shingles, and of the Territory east of the Cascade Range, 6,190,006 ft. of lumber and 2,700,000 shingles.

Brain Food.

You can no more crowd intellectual food into people's minds in quality and quantity, and at times of your own choosing, than you can make the child or the animal eat whatever you desire when not hungry.

You may make a newspaper of elaborate dimensions, and fill it up with a mass of reading that but few people want, and sell it at almost any price, and but few people will take it continuously.

Again, you may fill it up with a good deal of good information, without going to the care and expense of having it nicely prepared as to variety, arrangement, seasonable news, propositions clothed in good language and prepared to good taste, and your literary duty will not be appropriated or made useful to the community if too cheaply or recklessly set forth.

Again, it is easy enough to prepare a dish that is inviting at the first taste, when one does not care a fig about what they say, except to make their paper attractive for the time being, or until the fallacy of their spicy and mis-called "enterprising" articles come to their true color in the light of true information.

He who buys his literature by the yard or pound, instead of by its true standard of real worth, regardless of bulky quantity, not only deceives himself badly, but in the most important of all considerations, for a man who cheats his heart and brain, does himself the greatest of wrongs, for it is irreparable; it is perpetual; its injury goes down the ages, multiplying its important results in its influence from individual to individual.

A man has but one life to live. If he fills his mind with poor trash, there is no means by which he can cleanse it and begin anew, for the injury mars his thought or pollutes his character forever.

It is but little, at most, that is expended for literary food compared with other expenditures for human existence. Then why should people foster second quality literature, when the saving at most can be but a few dollars a year between that and buying the best.

Why will not people take more pains to inform themselves as to which publications are the best and most suitable for advancing their minds and their material interests as well than they ordinarily do? They are often careful (yet seldom careful enough) as to what seed they sow upon their land, and why should they not be equally careful and select of the intellectual seed they secure for themselves and others in their care?

It is a mistake to suppose that in consequence of the assignment of P. W. Smith & Co. work is suspended in Winchester district. Much ore is sacked awaiting transportation to the mill, and the showing for a big mine in that district is as good as ever. Those mines are now in the hands of J. B. Haggin and George Hearst, which goes to prove that in the near future they will be made to prove what they are, and the assays made show that they are well worth the price paid for them.

Useful Information.

How the Weather Indications are Determined.

At the Signal Service Bureau in Washington the weather indications are recorded at 5 A. M., 11 A. M., 4 P. M. and 11 P. M., daily. A reporter undertakes to tell how the work is done, and this is what he sees:

Take a seat in the indication room with me, and we will see how the weather is gotten up. It is now 4 o'cock, Washington time, and telegrams are pouring in from all parts of the United States, Canada, British America, West Indies, Nova Scotia, and falling into the lap of the sergeant in charge. The territory covered is from Olympia, in Victoria, on the northwest coast of British America, across to Sydney, above Newfoundland, thence down to Havana, across to San Diego, California, and thence back again. There's a girdle for Puck. At a certain hour of the day—3 o'clock, Washington time—observations are taken at all the stations, and then they begin to come in, chasing each other over the wires pell mell, like a crowd of unruly school boys. These dispatches are culled off to six gentlemen, each of whom sits before a map, one noting the thermometer, another the barometer, a third the condition of the weather, and so on. These are transferred to one large map, and then Old Probabilities makes his appearance. He glances over all; sees where a storm was at 1 A. M., and notes where it was at 3 o'clock. He takes into consideration the wind currents, the humidity, and all the minor details which his experience and learning have taught him. Not a word is spoken in the room. Old Probs. is in deep study. In a minute he will speak to 50,000,000 of people, and a few more over in Canada. His stenographer appears, and the indications are dictated for New England, then the Middle States, the South, West, Mississippi Valley, and then, perhaps, a storm bulletin 24 hours in advance to warn some special section.

Among the innovations made is the furnishing to sections of the country special reports of floods, the conditions of rivers, and their probable rise and fall, within 24 hours following, at given points. Then reports are made for Southern States on the weather during cotton picking time, signals being displayed from the telegraph stations denoting clear or bad weather coming.

Damage to Lead Pipes by Rats.—In the cellar of a house in Berlin a large number of rats had recently taken up their permanent abode. Notwithstanding traps and poison, the vermin could not be got rid of. The brickwork was carefully examined, and a good many holes were discovered, which probably served as nests for the rats, or led to the outside soil. All the openings were filled with cement, and the walls of the cellar pointed. The floor, which had hitherto been loose, was laid with bricks and cement. The rats disappeared, but after a short time a wet spot was observed in the brickwork, near where the water supply pipe ascended. On examination, a number of dead rats were found in a space of the cutting made for the pipe, which had not been filled up when the pipe had been moved, and close by the lead pipe had been gnawed right through. The above may be very easily explained. A family of rats had settled in the cutting; exit had been cut off by the closing up of all the holes; the rats, trying to get out, had attacked the lead pipe as being the softest material in their prison. They gnawed until they had made an opening, when they were drowned by the outflowing water.—*The Builder.*

The most essential fire apparatus, after all that may be said and done, consists of a few pails of water always kept in readiness. Their importance is shown by the fact that it is a matter of record that of the losses in mills paid for by the insurance companies, twice as many fires are put out by the pails as by any other means. These pails must be kept full, and used for no other purpose whatever. The best fire pails are made of strong galvanized iron, without covers, and they will last much longer if painted with hot coal tar, asphaltum, or some of the roofing compounds. This also helps to preserve the pails, as their black color makes them easily distinguished from other pails used for washing or drinking water. It should be the duty of some individual to keep the pails full, examining them at least once each week and replenishing the whole of the water before it becomes foul.

Luminous Paint for Railroad Cars.—A party of gentlemen recently made a trip on the Southeastern railway, in England, with the object of testing the luminosity of a railway car, a portion of the interior of which had been coated with Balmain's patent paint. The weather being dull, the zinc plates, which had received three coats of the paint specially hardened, were less sensitive than would have been the case, had sunshine struck directly upon them; but notwithstanding, on entering Blackheath tunnel, an agreeable, equally diffused light proceeded from the ceiling of the compartment and the two ends, the advertisements on which were seen clearly. The hands of a watch were also easily discerned, and the headings of newspaper articles read. Containing no phosphorus, the paint was without smell.

Hard Woods.—Chestnut and butternut are not very extensively sold for finishing, for which the better grades are selected, and their sale is dependent more on the question of taste than real superiority. The poorer stuff is used in common ways, and is best worked off when other woods used in manufacture are scarce in the dry, and the call stocks can be employed as a substitute on a pinch. Basswood is considerably sold for use in furniture. The black or red birch, which largely resembles cherry, figures somewhat as a finishing wood. The yellow is not valuable in the same way. Beech enters into the manufacture of chairs, tool handles, brewers' shavings, etc. Elm is made into cheap furniture. Yellow pine is very slow in gaining a hold upon popular favor. It is used by a great many operators who speak highly of the lumber, but it is far from having a boom. Generally buyers do not take to it kindly. What is used is mainly for flooring and finishing. Though the boards and planks are a subject of considerable complaint on account of imperfection in manufacture, the flooring is conceded to be turned out in good shape. Where high grade flooring is wanted, yellow pine is regarded the best and cheapest, but where a low or medium grade is desired, the wood must give way to white pine. The latter is sold much cheaper than the yellow pine, for when freights are added to the price of the lower grades the yellow pine can hardly compete.—*N. W. Lumberman.*

Cutting Glass by Electricity.—Mr. Fahdt, of Dresden, uses metal wires which have been made red hot by electricity for cutting glass. The apparatus consists of two screws, which are fastened on a plate at a distance from each other varying with the size of the object which has to be cut. The screws are in communication with the poles of a battery, and carry at their tops a metallic wire, which is placed round the object which is to be cut. The glass is carried by supports. When the circuit is closed the wire becomes red hot, and the places where the wire touches the glass (the glass can be turned round by the hand) become heated, so that by sudden cooling, or the contact with a humid body, a severance of the glass takes place. In order to remove the inequalities on the sections which have been obtained, the glass pieces are placed on an apparatus in which the section is exposed to the flame of a chalumeau, the glass piece being made to revolve, in order that all parts are touched by the flame. The glass is then taken to a heating furnace in order to prevent the heated parts becoming broken by too quick cooling. The glass is then removed to a room where it is left to cool.

Sawed veneers preserve the natural color and grain of the wood better than sliced.

Good Health.

Lead Poison.

Of all the metallic poisons lead is perhaps the one most often taken into the human body. It is eliminated from the body with more difficulty than the other poisons, and excepting those which directly kill, its effects are the severest and most varied.

Lead may enter the human system through the mouth, in water from lead pipes, or from type held in the mouth by compositors. It may be taken in through the lungs by breathing, in lead factories of various kinds; be absorbed by the mucous membrane of the nose from snuff containing it. It may be taken in even through the unbroken skin from hair dyes and rouges, and through both skin and nostrils by painters.

Some persons are much more susceptible to it than are other persons.

Among the symptoms that show that it has been taken into the body are colic, great muscular weakness, constipation, female disorders, blindness, complete or partial, neuralgias of the head, face, joints, in the small of the back, between the ribs, or in the upper or lower limbs, loss of sensibility in the skin, alternating with over sensibility, muscular spasms, and finally and most frequently, paralysis, which may affect almost all the muscles of the body. One of the most constant signs of the presence of the poison is a blue line along the gums.

As the system, left to itself, gets rid of the lead very slowly, the lead accumulates in it until what was for a while harmless may become a fatal poison.

The treatment should aim to palliate the pains and to quicken the eliminating organs. But the fundamental thing is to invigorate and improve the general health by pure air, nutritious diet and warm baths. Cold baths injure.

There is good authority for the statement that workers in lead factories who drink milk several times a day are unaffected by the lead. —*The Companion.*

A Reliable Pill for Dyspepsia.—Diastase, 10 grains; pepsine, 50 grains; extract of gentian, 50 grains; tartaric acid, 50 grains; powdered rhubarb, 50 grains, and gentian, q. s. Divide into three-grain pills. Dose, two to three pills, shortly before meals.

Cause and Cure of Rheumatism.

Common rheumatism is a disease which affects the joints, the hinges of the body, in such a way that the slightest motion of the ailing parts gives pain. A creaking hinge is dry and turns hard. A single drop of oil to moisten it makes a wonderful change, and it instantly moves on itself with the utmost facility. All kinds of rheumatism are an inflammation of the surfaces of the joints. Inflammation is heat; this heat dries their surfaces; hence, the very slightest effort at motion gives piercing pain. In a healthy condition of the parts, nature is constantly throwing out a lubricating oil, which keeps the joints in a perfectly smooth and easy-working condition. Rheumatism is almost always caused—indeed, it may be nearer the truth to say that it is always the result of a cold dampness. A dry cold or a warm dampness does not induce rheumatism. A garment, wetted by perspiration or rain or water in any other form about a joint, and allowed to dry while the person is in a state of rest, is the most common way of causing rheumatism. A partial wetting of a garment is more apt to induce an attack than if the entire clothing were wetted; because, in the latter case, it would be certainly and speedily exchanged for dry garments. There are two very certain methods of preventing rheumatism. The very moment a garment is wetted in whole or part, change it or keep in motion sufficient to maintain a very slight perspiration until the clothing is perfectly dried.

The failure to wear woolen flannel next the skin is the most frequent cause of rheumatism; for a common muslin or linen or silk shirt of a person in a perspiration becomes damp and cold the instant a puff of air strikes it, even in midsummer. This is not the case when woolen flannel is worn next the skin.

The easiest, most certain and least hurtful way of curing this troublesome affection is, first, to keep the joint affected wound around with several folds of woolen flannel; second, live entirely on the lightest kind of food, such as coarse breads, ripe fruits, berries, boiled turnips, stewed apples and the like. If such things were eaten to the extent of keeping the system freely open, and exercise were taken, so that a slight moisture should be on the surface of the skin all the time, or if in bed the same thing were accomplished by hot teas and plentiful bed clothing, a grateful relief and an ultimate cure will very certainly result in a short time. Without this soft and moist and warm condition of the skin and an open state of the system, the disease will continue to torture for weeks and months and years.

Inflammatory rheumatism may, for all practical purposes, be regarded as an aggravated form of the common kind, extended to all the joints of the body, instead of implicating only one or two. For all kinds, time, flannel, warmth, with a light and cooling diet, are the great remedies.—*Hall's Journal of Health.*

Shaving the Beard.

The more I reflect upon the mysteries of neurology and animal chemistry, the more confident I am that while we are the least suspecting it, trifling errors in our daily life are producing important effects upon our corporeal systems; and I declare it as my deliberate conviction, that the habit which may almost be styled American, of using the razor upon the face, is sufficient to cause a large proportion of the lamentable evils which affect the human race in this country.

It appears by experiment that the beard, if shaved, grows four to five times faster than if unshorn. In this calculation an item is omitted which it is difficult to estimate, *i. e.*, the stimulus given the beard by the first application of the razor in adolescence, the experiments being made upon beards after they have acquired an unnaturally rapid growth. The effect of this early stimulus may be fairly counted at double the natural growth; then reckoning the difference in size and weight of the fiber, which is treble, and we find the frightful truth to be that we raise 30 times the natural quantity of beard! Thus, it is evident that the true beard is exhausted at a very early age, after which the system is forced to supply a substitute. Now, nature will not submit with impunity to extraordinary demands upon her vigor, and that which requires her to produce in a lifetime, 30 times as much beard as she was first inclined to, must certainly be considered as such. She is fatigued in proportion to the effort, let the particular kind be what it may although her recuperative powers are great, she insists upon having repose, even when working at a rate chosen by herself. If that repose is denied her, she takes her revenge by breaking down the mechanism.

Upper Rooms Healthiest.—At a recent sanitary Congress in England the Hon. F. A. Russell said that it was found that in the upper rooms of a house a drier atmosphere prevailed than was found in lower levels. Such rooms are also more comfortable in cold or foggy weather. The practical conclusions seemed to be that invalids and delicate persons should generally be placed in high and sheltered situations, in the highest rooms of a house, and by no means on the ground floor; that every house ought to be built on arches, or thoroughly ventilated underneath; that no house not so ventilated should be considered habitable.

TABLE OF CONTENTS.

EDITORIALS—General Arrangement of Silver Mills; Investigation of Mining Companies, 353. The Denver Exposition—No. 15, 358. Passing Events; Water Used in Quartz Mills; Assessment Work in Mining Claims; A Useful Journal; Decision Against Careless Miners, 360. Automatic Fan Recorder for Mines; Foundations for Batteries, 361. Notices of Recent Patents, 364.

ILLUSTRATIONS.—Section Showing General Arrangement of the Machinery in a Silver Mill, 353. Hall's Self-Regulating Fan Indicator, Showing Diagram of Water Gauge and Speed During Six Hours, 361.

CORRESPONDENCE.—Notes from Eureka, Nev.; Letter from Denver, 361.

MECHANICAL PROGRESS.—Usefulness of Technical and Trade Journals; A New Steam Engine; Iron Supports; Edge Tools; Tires of Mixed Metals; Misdirected Mechanical Ingenuity; Responsibility, 355.

SCIENTIFIC PROGRESS.—Practical Scientific Research; Light in Vacuse; Torpedoes Doomed; Does the Sun Lose Its Heat; The Color of Pure Water; Effect of Sunlight upon Glass Surfaces; A Printing Press Run by Solar Heat; A New Carbon Arrangement; Still Another; Burning Gas Without Flame, 355.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 356.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana and Utah, 356-57.

USEFUL INFORMATION.—How the Weather Indications are Determined; Damage to Lead Pipes by Rats; Luminous Paint for Railroad Cars; Hard Woods; Cutting Glass by Electricity, 359.

GOOD HEALTH.—Lead Poison; A Reliable Pill for Dyspepsia; Cause and Cure of Rheumatism; Shaving the Beard; Upper Rooms Healthiest, 359.

NEWS IN BRIEF—On page 364 and other pages.

MISCELLANEOUS.—Rapid Growth of Arizona; A New Style of Steamship; An Improved Coil Spring; Railroads Wanted for Mines in Arizona; Successful Concentrators; Forest Trees of California, 354. Cost of Mining in Sweden; New Foundry Enterprise, 358. Pacific Coast Lumber Interest; Brain Food, 359.

Business Announcements.

Engraving—Crosscup & West, Philadelphia, Pa.
Sulphurets—A. B. Watt, San Francisco, Cal.

Passing Events.

From what we can glean from the mining localities in this State, a favorable mining season is anticipated nearly everywhere. From other regions equally favorable reports are received.

The only new feature to note in mining matters is the project which the Idaho Mining Co., of Nevada county, has on hand, regarding the introduction of water for the purpose of doing the work about the mine, and entirely ridding the premises of steam. The local papers say that when this is done there are numerous mines now idle that will follow their example and dispense with steam. It is stated on good authority that $9 and $10 rock would yield a handsome dividend, provided ample water power could be obtained to run the mill and mine. There are but few ledges around that section but what will pay all the way from $8 to $12 per ton, and therefore the prospect of water being introduced as a power to work with, is looked forward to with a great deal of interest and hope. The Idaho company have not yet definitely decided to run their ditches to convey the water to their mine, but there is every reason to believe that they will shortly do so, as Messrs. Edward and John Coleman and the stockholders of the Idaho company all think most favorably of the project.

ROBERT MAYFIELD and Alex King, colored men, were lowered into the slack of the furnace at Birmingham, Alabama, in which the fire was supposed to be dead, to make some repairs. The fumes overcame them, and they dropped upon a hot mass of ore and coal below and their bodies were reduced to cinders.

Water Used in Quartz Mills.

The quantity of water consumed in the batteries varies with the character of the ore and the degree of fineness to which it is crushed. Usually in the mills of Washoe the consumption is between 250 and 300 cubic feet per ton of rock treated, or from one-third to one-half of a cubic foot of water per stamp per minute; but this includes the water used in the pans which does not pass through the batteries.

At one mill on the Comstock cited by Mr. Hague the supply tank contains 4,400 cubic feet of water, which is sufficient for eight hours' work of full duty. The mill has 24 stamps, which crush 55 tons of rock per day, discharging at only one side of the mortar, through a No. 6 punched screen. The consumption in this instance is equal to 240 cubic feet of water per ton of rock, or .38 of a cubic foot of water per stamp per minute. Making a due allowance for a portion of the water used in amalgamation, without having passed through the batteries, the quantity actually used in crushing in this mill does not exceed one-fourth, or possibly three-tenths of one cubic foot per stamp per minute.

The method of measurement in the delivery of water is by "miners' inches." A "miner's inch" is the quantity of water that will pass through an orifice one inch square in the side of the measuring box under a head, usually of six inches. The measurement is not uniform throughout the country, as different heads are used in different places. Generally, however, in California, the aperture is made two inches deep and as long as need be, in order to furnish the requisite number of inches, and the water in the measuring box, which is at one side of the supplying flume, is allowed to attain a hight of six inches above the center of the orifice.

The quantity of water that will pass through an orifice of one inch square in the side of the box, under a head of six inches, determined by multiplying the area of the orifice by the theoretical velocity $\sqrt{2gh}$, and taking two-thirds of the product as effective discharge, is .02633 cubic feet per hour. The mill just referred to uses five inches of water. Assuming that its measurement is uniformly in accordance with the above conditions, the amount delivered in 24 hours is 11,361 cubic feet, equal to about 206½ cubic feet per ton of rock treated. Taking the operation of the mill referred to as a criterion, one inch of water is a supply for five stamps, including the quantity required for amalgamation as well as for crushing.

Another calculation is that each stamp of a mill uses 10 pounds of water in a minute; each pan uses 16 pounds a minute, and each settler uses 9 pounds a minute. If water is run from a mill into settling tanks it can be saved with a loss of 20%. This will make the *actual* supply of water required in pounds per minute to be as follows: for 1 stamp, 2 pounds; 1 pan, 3.2; 1 settler, 1.8.

In the circular of the Union Iron Works, of this city, are given some figures which show the water required for a 60-stamp mill. They are as follows: 225 horse power (the total power required) will require, per minute, 169 pounds; 60 stamps will require, per minute, 600 pounds; 22 pans, 352 pounds; 11 settlers, 99 pounds; total water required, 1,220 pounds.

Of this 1051 pounds used for pumps, pans and settlers can be repumped to the tank at a loss of 20 per cent.; and the 169 pounds for the engine can be condensed at a loss of 50 per cent. This will leave the actual amount to be supplied as follows:

20 per cent of 1,051 pounds	210.2 pounds
50 per cent of 169 "	84.5 "
Total water required	294.7 "

This calculation is based on the supposition that a 60-stamp mill requires a total of 225 horse power, and the following table, from the same source, shows how this is made up:

60 stamps @ 1½ horse power	67.5	horse power
22 pans @ 4 horse power	88.0	" "
11 settlers @ 3 horse power	33.0	" "
3 concentrators @ 2 horse power	6.0	" "
1 rock breaker @ 2 horse power	5.5	" "
Friction	25.0	" "
Total power required	225.0	" "

Of course this is intended as a calculation for a large mill, but it will be easy for anyone to figure out from what we have given almost exactly what water will be required for a mill of any size.

MARIPOSA MINES.—The Mariposa *Gazette* says: We have, within the past year, seen and conversed with several well-known experts who have traveled the length and breadth of the Pacific coast, including Colorado, Nevada, Arizona and New Mexico, who say the mines in this section and county compare favorably with any they have seen, and they believe the inducement for capital is greater and better here than elsewhere, for the reason, most of the veins are prospected, and a certain knowledge as to their respective value can easily be acquired. The numerous and inexhaustible gold bearing quartz veins in the section which embracee Sherlocks, Whitlocks, Saxtons, Sweet Water, all within an area of 20 miles square, will, within the next 30 years, prove to be one of the most populous and valuable mining districts in the State.

THE Idaho Gold Mining Company have reduced their dividends this month to one of $2.50 per share, aggregating $7,750. Total of dividends to date, $3,318,500.

Assessment Work on Mining Claims.

The first of January will soon be here, and negligent miners are again reminded that they must do the work required by the laws of the United States on or before that date, or they will be liable to lose their claims. Plenty of time and warning has been given, and claim owners will have no one but themselves to blame if they forfeit their rights by not attending to their property in time.

If certain claims are of any value, they will not be abandoned by the locators, and it will probably happen that some of the "jumpers" will get fooled in some cases, supposing that work is not done because it has been neglected until late. As a general thing, however, none but claims of some value will be liable to be jumped, and many of these have no doubt been "spotted" by this time by parties on the lookout for just such chances. A good many miners will, of course, put off doing the necessary work until the last minute, intending to commence on the first day of January. Those who are left out in the cold by procrastinating can blame only themselves.

The best way, no doubt, for *bona fide* locators to do, is to patent their claims at once. This will save annual expenditure and give a good title at the same time. A patent is a very good thing to hold in case of a sale. The English purchaser of mining property will not look at anything which is not covered by a United States patent, and it is an incentive to any purchaser to know that he is sure of a good title.

In this connection it is proper to suggest to locators the propriety of having the original location properly surveyed by a competent surveyor, so as to have a perfect record to proceed upon when making application for a patent. The careless way in which measurements are usually made in original locations makes it difficult to get the official surveys for patents in accordance with the legal regulations. A lawyer in this city told us not long since that in more than half the cases where patents were wanted it was impossible to get the surveys to correspond with the original record of location. In many cases the ground was formally relocated to save trouble. It is always best to have preliminary survey made before taking steps toward applying for a patent.

Loss of Quicksilver in Milling.

The loss of quicksilver during the operation of working ores by the Washoe process arises from two sources—one mechanical and the other chemical. The former depends largely upon the manner in which the final washing from the pulp is conducted, the separation being more or less perfect according to the skill and care with which it is executed. A considerable quantity of the metal, however, is so cut up and ground to such a fine state of division that it is impossible to save it. The chemical loss is occasioned by the formation of the chlorides of mercury, which escape with the tailings.

In the patio the chemical loss is frequently very considerable; the amounts of common salt and magistrale employed are large, while at the same time there is no reducing agent present to act upon the calomel formed, as is the case in the pan. In the patio the loss is said to increase in proportion to the richness of the ore in the sulphurets of silver, owing to the fact that for every atom of chloride of silver reduced by the mercury, a corresponding atom of the latter metal is consumed as sub-chloride.

In the Washoe process the chemical loss would seem to be small in proportion to the entire consumption. This is probably due to the beneficial effects of the iron which combines with the chlorine of the calomel, setting the quicksilver free. The more the metal is ground the more it must be cut up, and the greater difficulty in recovering it. Now if the consumption of iron is assumed to measure the grinding effect exerted by the pan, the relation between the loss of the mercury and that of the iron should be in a certain degree proportional.

The following table, compiled by J. D. Hague from the results of several mills, furnishes some interesting details in regard to the loss of mercury:

Part one shows that the loss of mercury is independent of the consumption of chemical agents. Part two shows that the loss of mercury is in some measure dependent upon the consumption of the iron of the pan.

TONS OF ORE.	I. Pounds per ton of ore.				II. Pounds per ton of ore	
	Salt.	Sulphate of copper.	Sulphuric acid.	Mercury.	Iron.	Mercury.
5,400	.....	0.33	0.18	1.54	9.42	1.54
8 605	.....	1.74	0.31	1.39	9.79	1.38
4,703	0.23	1.52	.....	1.34	9.39	1.38
35,000	9.00	3.00	.....	1.33	7.50	1.33
7,523	.....	1.38	.....	.79	7.14	1.00

The following is the result of an analysie of some artificial crystals of Washoe amalgam:

Mercury	75.04
Silver	24.18
Gold	.77

They have the composition very closely of three atoms of mercury to one of silver.

A Useful Journal.

A man who is following mining as a business, in order to keep abreast of the times and take advantage of everything that is new, must be told what is new. He cannot plod along at his mine or mill, working all the time, and find very many hours to experiment. He has not much time to investigate problems connected with his business, and must often take the experience of others to guide him on his way. But how is he to get this experience of others except by reading some journal which makes a point of collecting all the experience for just this purpose?

Such a paper is the MINING AND SCIENTIFIC PRESS. It has been constantly—every week since 1860—presenting to its readers the new things as they come up. It not only describes well the new appliances, machinery, etc., but the details of the new processes, new methods of mining, and everything of interest in that connection.

In truth it seems difficult to think that a man who is connected with mining would try to do without such a journal. Not only is he told of the current news concerning the mines everywhere, but every possible economy or improvement brought to bear on the business of mining or metallurgy is described and explained to him. He receives many little hints that are worth far more than the mere subscription price of the paper.

The editors and publishers of the MINING AND SCIENTIFIC PRESS feel no hesitation or modesty in urging the claims of this paper upon all persons in whose special interest it is printed. Being the only technical journal of the kind on the Pacific slope, and having a wide circulation in all the old and new mining regions, and among the most intelligent and progressive people of the coast, it presents a fine medium of advertising—a feature which our columns show is appreciated.

New subscriptions can be sent by mail at all times. Those who think they have friends who might be benefited by, or interested in, the paper, will confer a favor both upon them and us by calling their attention to this matter, and at this time. By so doing they will place us under still greater obligations to themselves, and enable us, by its increased receipts, to add still more to the value of the paper. It is thus that in the growing welfare of the country and people this journal hopes to find its due share of prosperity and a fair reward for its efforts in behalf of science, of industry and of progress.

Decisions Against Careless Miners.

In a recent article on the causes of mining accidents we referred to the fact that most of the accidents were due to mere carelessness of the men themselves. Most of the companies endeavor to provide against accident to their employees, and it seems not difficult to collect damages from them if they are negligent. Still, it seems unjust to hold the company responsible for accidents that occur through the carelessness of operatives.

In the United States Circuit Court at Carson, in the case of Buckley vs. the Gould and Curry Mining Company, Judge Sawyer gave his decision recently, in which Judge Sabin concurred, that the owner of a mine is not responsible for injuries sustained by a miner working underground through the carelessness of an engineer on the surface, hoisting and lowering men and material by machinery while performing their respective work. The responsibility for harm of this sort does not extend further than to the co-workers underground, who, the law presumes, will take proper prudential steps to protect themselves against the negligence, untrustworthiness or lack of skill in their companions in labor.

Another suit just decided settles another point of interest to miners. The suit of Michael Clancy against the Union Consolidated Mining Company for $25,000 damages for injuries received in December, 1879, through being hoisted up into the sheaves, which has occupied the United States Circuit Court for two or three days, was decided in favor of the defendant by the verdict of a jury. Clancy sued for a sum equal to $4 per day, with interest, from the time of the accident. What the plaintiff founded his case upon was the fact that the indicator was out of order, and the engineer was running by tags fastened upon the cable when the accident occurred. The defense showed that the shaft had been sunk to nearly its full depth by tags on the cable, and that the only advantage derived from the use of the indicator was that it allowed the engineer to lower and hoist at greater speed. The majority of the shafts on the Comstock were sunk without the use of the present dial indicator.

MR. R. E. C. STEARNS, who resigned some time since the Secretaryship of the Board of Regents of the University of California to accept a position in the U. S. National Museum, in the Department of Conchology, has been compelled to forego his purpose on account of ill health. It was his intention to go on to Washington and enter upon his duties there very shortly, but by medical advice he will remain on this coast

Automatic Fan Recorder for Mines.

Hall's self-registering fan indicator is a device which may be placed in the superintendent's office—the engine man never sees it—and is practically independent of distance. Mr. C. M. Percy, who is publishing in the *Colliery Guardian* extended articles on the mechanical engineering of collieries, thus describes the indicator: "The engraving will give an idea of the action of Mr. Hall's arrangement, and is supposed to represent the diagram of pressure and speed from 12 o'clock mid-day to 6 o'clock in the evening. Only one-half the diagram form is shown; each really represents, as already explained, the work of a day and night. The paper on which the diagram is traced is divided round the circle into 24 divisions, each division representing an hour, and each hour can have as many subdivisions as are desirable, the usual practice being to let each subdivision represent one quarter of an hour. The paper is marked for water-gauge up to six inches, and each inch is further divided into tenths, although these are not represented in the figure, to avoid confusion.

At the Bickershaw collieries each 250th revolution of the fan is shown by a vertical line, but in the figure we have supposed only each 500th revolution to be marked, and with a speed in the fan of 41 or 42 revolutions per minute this would divide with a regular velocity each hour into five spaces. The irregular line round the circle represents the water gauge, and is shown as varying from about 3.3 inches to 3.6 inches. The variations of water-gauge are, perhaps, exaggerated, but these exagerations only show with a little more clearness in the figure what the indicator does. Of course, the diagram forms are changed each day at the same hour, and those taken off should be pasted in a book especially kept for the purpose, one book containing, when complete, the records of a whole year. It is hoped that the figure, along with the text, will have made the action of this self-registering indicator clear, but it is not easy to do justice to its merits or to understand its simplicity and efficiency except by personal inspection.

It was originally intended to say something as to the capabilities of fans of given dimensions, but it will probably be wiser not to attempt to lay down any rules as to the quantities of air which fans will discharge. Any such rules would only be correct under certain circumstances, and would simply mislead the reader, because everything depends on the conditions of the mine or mines through which the air has to pass. In chapter 25th particulars have been given as to the actual work being done by 19 fans of various kinds, varying in diameter from seven feet to 46 ft., and with velocities varying from a little over 3,000 ft. per minute to nearly 7,000 ft., and dealing with quantities of air varying from 60,000 cubic ft. to 300,000 cubic ft. per minute. Such practical results will be a far better guide than merely theoretic rules. So many fans are now working that the most reliable lines for those who propose erecting a fan are to obtain as much information from as many places as possible where fans are at work. No body of men are more willing to assist their fellows in matters of this kind than mining engineers.

Messrs. Walker Brothers, who have had very large experience in fan construction and erection tending over 20 years, in one of their excellent fan catalogues give the following table showing the approximate volumes of air exhausted by fans according to diameter, and taken from actual experience:

Diameter of fans.	Width of fans.	Volume of air per minute.
10 feet.....	3 to 4½ feet.	20,000 cubic feet.
12 "	4 " 5 "	35,000 "
16 "	6 " 7 "	55,000 "
18 "	7 " 8 "	65,000 "
20 "	7½ " 8½ "	75,000 "
24 "	8 " 9 "	85,000 "
30 "	10 " 11 "	110,000 "
35 "	12 " 13 "	150,000 "
40 "	12 " 14 "	200,000 "
46 "	12 " 15 "	250,000 "
50 "	12 " 15 "	300,000 "

The very sensible note is attached to this table that the volumne of air exhausted by fans depends very much upon the condition and dimensions of the airways in the mine. It not unfrequently happens as a consequence of this, that fans of similar diameters do not give equal results at different collieries, and the above data are approximate only.

The finest gold ever assayed at the United States Assay Office, New York, was recently received from the mines of the Canada Consolidated Gold Mining Co., of Ontario. Of two bars, aggregating nearly $2,000, one was 992 fine, and the other, of about $1,200 was 998 fine. One small bar even ran 999. The gold was produced by chlorination from the gold-bearing arsenical sulphurets treated by this company. The assays show that from 90% to 97% of the gold is obtained by this method.—*Engineering and Mining Journal.*

The flood of water from the Sutro tunnel is 6,874,632 gallons every 24 hours. It has a temperature of 112°.

Notes from Eureka, Nev.

[From our regular Correspondent.]

Our camp jogs along in its quiet way. Nothing has transpired during the past week to break the ordinary routine of mining life on the Bass Range. The mines are yielding their usual quantity of ore, and the furnaces are turning out their usual quantity of bullion.

It is thought that the Richmond mine is showing an increase of ore in sight. It is true that no one has said there is such an increase. The Richmond employees, like the company, are very reticent about everything that concerns the mine, and nothing can be learned from either, except from signs. Some of the company's miners look knowingly and say that the mine is not played out yet. At the reduction works everything looks quiet, but an air of confidence is noticeable in everybody about the place. In the foundry a bed, or bottom plate, is being cast for a new style of a water-jacket furnace, to be built shortly. At the refinery, the largest on the Pacific coast, only one melting furnace, one crystalizer, one cupel, and one reducing furnace are running; but it is thought that the work will soon be increased.

There is a good deal of active life on Adams Hill, which is situated just north of Ruby Hill. The Altoona mine is now under lease to a party of miners, who reasonably expect to make money out of it. The main shaft is down only 72 feet from the surface, yet more than 250 tons of ore, averaging $95 per ton, has been taken from the mine. A good prospect is the May mine, recently leased to Messrs. Steward & Co. Sixty tons of ore taken from it average $93 per ton 4 tons averaged $800 per ton, and run a drift 4x6 ft., 80 ft. from the new shaft, to connect with the old works. The ground is open and loose, with immense deposits of low-grade quartz in sight. There is also high-grade ore in large quantities in the mine.

A few days ago the tributers in the Williamsburg mine sent 30 tons of fine heavy galena ore to the Eureka Con. furnaces. Seven tons of ore from the Mountain Boy mine, shipped to the Eureka Con. last Friday, realized $1,750. On the same day the tributers in the Phœnix mine sent 30 tons of ore to the same furnaces, valued at about $80 per ton.

There are also 200 sacks of ore from the Metamoras mine on Prospect mountain awaiting reduction. For the past four or five days the teams have been engaged hauling an average of about 16 tons of ore per day from the Dunderburg mine to the Richmond furnaces. Considerable ore has also been shipped from the Home Ticket mine. Work will shortly be resumed on the Golden Rule cross-cut with very good prospects ahead, when a new shaft is to be sunk about 50 ft. from the Home Ticket incline, for the purpose of prospecting the Clipper ground.

The average shipment of ore from the Eureka Tunnel has been 8 tons per day for the past week. The air is now very good, and everything about the mine looks prosperous. The last shipment that was made to the Eureka Con. furnaces worked $130 per ton. During one day of the week car samples averaged $165 per ton.

Last Thursday 21,685 lbs. of ore shipped from the silver mine on Prospect mountain to the Eureka Con. furnaces gave to the owners $37.99 in silver and $53.55 in gold per ton. There are 20 tons of ore valued at $90 per ton on the dump at the Fair Play, on Alhambra hill. This is low grade for that mine, and is shipped as "second class." The mines on Silverado mountain are all looking splendid. The Berry-

HALL'S SELF-REGISTERING FAN INDICATOR, SHOWING DIAGRAM OF WATER GAUGE AND SPEED DURING SIX HOURS.

at present the average assay value of the ore being extracted is $220 in silver and $40 in gold. The Horace Tony mine has been leased to Charley McDonald & Co. From the main shaft, down 70 feet, over 100 tons of ore has been taken, the value of which was from $15 up to $240 per ton, in silver and gold. There is another shaft, down 30 feet from the surface, which shows a fine body of heavy galena ore. McDonald has leased this property, with the intention of prospecting for a continuation of a valuable ore body now being developed in the Membere mine. He is sinking a new shaft within 20 feet of the same, and expects daily to find it.

Messrs. Molino and Frazer have taken a lease of the north-western portion of the Silver Lick series for a period of four months, and have already good quartz ore in sight. These gentlemen are splendidly equipped for prospecting, even to an assay office, which they have fitted up for the purpose of doing their own work in that line.

In the Maine mine, of the Silver Lick series, the usual work is going on. The prospect continues good, and large quantities of ore are being shipped to the furnaces.

The extention of this property, the Herculean, is developing into a mine of importance. Six men are constantly employed extracting quartz for the Albion furnaces. This is found in irregular depoeits, and assays from $20 up to $150 per ton. Of the latter quality there are about 75 tons on the dumps, and plenty more of the same sort in the mine.

At the Eureka No. 2 mine two men are employed by the Wales Con. Mining Company sinking a shaft, which is all that is being done by them at present. There is no ore in sight. There is, however, a good house over the main shaft of the Wales Con. which is equipped with steam hoisting works, but the sound of the whistle is no longer heard.

At the Price and Davis shaft the hoisting machinery is being taken down for the purpose of removing the Albion mine, where it can now be used to good advantage.

At the Paul Pry a contract has been let to man brothers are working with good results in the Maryland tunnel. Lou. Dibber is getting out a large quantity of high grade quartz from the Western Globe, and will soon be ready to make a shipment to the reduction works. The men having a lease of the Silver Nugget have run a tunnel for the purpose of developing that mine. They cut a stringer about 150 ft. from the mouth, on which they have since sunk a winze following the vein which at a depth of 50 ft. opened out into a body of ore three feet thick. Assays run from $50 to $250, in silver and gold.

Silverado and Albambra hills, situated about 14 miles from the town of Eureka, and at one time famous for the quantities and richness of the ores produced, were for a long time cast in the shade through reckless management, but a new set of adventurers have taken hold, and the result of the change will some day be found in the development of some of the best mines in eastern Nevada. Yours truly,

M. H. Joseph.

Life-Saving Respirator.—This device, which is intended for the use of men working in lead mines, dry-crushing mills, lead smelting, quicksilver mines or works, bullion refineries, chemical works, etc., is now in the hands of Mr. H. H. Bromley, 43 Sacramento street, as general agent, he having the sale of these goods, which were formerly sold by Seth Marshall. This respirator is in great favor for preventing lead poisoning and salivation, and is in use all over this coast.

Superintendent McClellan, at Mill City, El Dorado county, is putting a large boiler in his mill to furnish hot water to the batteries, so that cold weather will not interfere with the running of the mill.

The first lot of tacks ever made in California have been turned out by the Judson Manufacturing Company at the works recently erected at Emery Station near Oakland. The manufacture of this useful article will now continue at the rate of about a ton a day.

Letter from Denver.

[By C. F. B., our Resident Correspondent.]

Editors Press:—In the words of the country newspaper, "now that the smoke of battle has cleared away," the people of this State are gradually returning to their old avocations. The general trade is good, the mines are in a flourishing condition, and, notwithstanding the weather, a great number of them will be worked all winter. So far our winter has been very mild, and has enabled miners and others to accomplish a great deal more than was anticipated. A great many buildings are still in course of erection here, and although the city has as busy an appearance as in midsummer, no one can witness the improvements that have been made and are still being constantly made in Denver without being forced to the conclusion that it will eventually become one of the largest cities in the west. Truly we have the wealth of the whole Rocky Mountain range from Wyoming to New Mexico to aid us in attaining that end, and we might, as has been done too long, ignore altogether our unsurpassed soil, which, with proper irrigation, produces as fine a quality of fruits and cereals as can be raised anywhere.

Colorado has made unprecedented progress in the development of her mineral wealth, in her manufactures and in her agriculture during the past year. The mineral output will exceed that of last year by nearly $5,000,000, leaving the State still at the head of mineral-producing States. The works of the Colorado Iron company, the Denver rolling mills and the vast plant of the Colorado Coal and Iron Co. have been constantly adding to our wealth. The value of the iron product of Colorado is immense, and is already attracting the attention of iron-masters and capitalists of the East.

Our coal and coke interests have taken a decided step forward, and the statistics relating thereto, if properly gathered, would prove astounding even to our own people.

During the year many thousands of acres of land have been brought under irrigation, and have yielded crops for the first time. The herds of our cattle and sheepmen, dotting the plains in every direction, form a large item in the general round-up.

The Mining Exposition held here during August and September last has proven to the world that we have the material, and only need time to develop our country into one of the richest spots upon the face of the globe.

I was shown a specimen of amalgam ore to-day which was taken from a mine in La Plata county, in the extreme southwestern part of the State. It is a combination of quicksilver and gold, and lays in sheets in the rock. It occurs in small streaks in a very wide vein, and runs $10,000 to the ton. This character of ore is found nowhere else in the State but in this mine. The property is owned by Eastern parties, who are erecting a 20-stamp mill on the ground, which will be ready for work early in the spring. This lower or San Juan country contains some of the richest mines in the State, and in a future letter I will undertake to describe some of the more important ones.

Denver, Col., Nov. 15, 1882.

Foundations for Batteries.

The foundation for batteries in stamp mills generally preferred in Nevada as well as in California consists usually of heavy timbers, standing vertically, placed close together, and firmly connected by means of cross timbers and bolts of iron. The timbers are from 6 to 12 ft. long, according to the character of the ground and the desired hight of discharge for the mortar. Sometimes they stand on a horizontal timber, so laid as to serve as the base of two or more batteries, and resting upon the ground, the surface of which has been previously removed and leveled down sufficiently for the whole number of batteries to be placed on a firm bottom. When the foundation timbers are in place, the space about them is packed and stamped as firmly as possible with clay or earth. Where the ground on which the batteries are to be built is a hard, compact gravel, or firm, clayey material, the surface is sometimes leveled off so as to admit of laying the transverse sill timbers of the battery frame, and a narrow pit is then excavated, only long and wide enough to receive the ends of the mortar blocks, and several feet deep, into which the posts or blocks are introduced, in a vertical position, their bottom ends resting directly on the ground, with any intervening horizontal timber. The remaining space in the pit may then be compactly filled with clay that is pounded or stamped firmly into its place. Sill timbers and the battery posts are securely bolted to the foundation timbers. The posts are braced by timbers and rods, and are connected by the tie timbers, which also support the guides.

CHICAGO **FRASER & CHALMERS.** ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Gryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Gur patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Gld Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

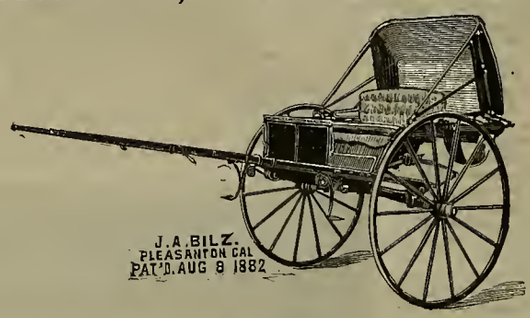
J. A. BILZ'S CARRIAGE MANUFACTORY,

Machine and Blacksmith Shop,

PLEASANTON, - - California.



I present above an exact representation of my new Excelsior two-wheelod Phæton, which is the result of long experiment, and with which I am willing to challenge competition by any other two-wheeled vehicle made. I guarantee that the chucking motion is entirely removed, and that for ease of riding, my Phæton is equal to any Buggy. The shafts are hung loosely in a rubber box, by which means the jar is completely removed from the axle and the horse's back. The body is also hung loosely on a round axle, and is balanced in front by two coil springs with eccentrics, which prevents the "jogging motion" that would otherwise be imparted by the horse. It is, therefore, as easy for the horse as for the rider.

The Excelsior Phæton

Is made in four different styles, ranging in price from $90 to $100. I also keep a large stock of Family Carriages, Open and Top Buggies, Spring Wagons and all kinds of Farming Implements, all of my own manufacture. I also manufacture my well-known VINEYARD and ORCHARD PLOW, which can be run close to trees without danger by the whiffletree. I am prepared to do all kinds of machine work.

N. B.—Parties from abroad who want to get the best article made, at reasonable prices, should address me for further information and reference.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

SAW-FILING MACHINE.—John Palm, Monitor, Alpine Co., Cal. No. 267,756. Dated Nov. 21, 1882. This invention relates to an apparatus for holding and filing saws, and it consists of a post or stand, which may be fixed to a bench or other support. This post has a slotted arm hinged to it by a joint, which allows of a horizontal or a vertical movement. A transverse bar is fixed at any desired point in this slotted arm, and the saw holder rests and is adjusted upon this bar so as to bring the teeth of the saw at the proper hight and angle for the action of the file, which is fixed in a guide so as to move across the teeth at any desired angle. The file is peculiarly constructed and supported in its guide so that it may be turned upon its axis.

GATE.—Charles A. Wyman, of San Jose, California. No. 267,765. Dated Nov. 21, 1882. This invention relates to the class of gates, and more especially to those which are intended to be opened by the passerthrough without having to alight from his conveyance. This invention consists in the arrangement of cords and levers hereinafter described, when applied to a swinging gate, whereby it may be unlatched and swung open by power applied to the cords hung conveniently within reach. The object of this invention is to provide such an arrangement of devices for opening gates as shall be operated with the greatest ease and to the best advantage.

VENTILATOR.—Michael H. Dorgan, S. F. No. 267,741. Dated Nov. 21, 1882. This invention relates to certain improvements in that class of ventilators which are swiveled upon the tops of soil-pipes, flues, etc., and it consists in a conical casing with spaced walls opening at the frustum into a cylindrical pipe, in which and in the opening of the cone is placed a double conical plug. The device is provided with a vane for keeping in the wind and with a suitable coupling swiveling it in place.

COUGH REMEDY.—Hannah Branch, North San Juan, Nevada Co., Cal. No. 267,738. Dated Nov. 21, 1882. This is a new and useful compound to be used in case of coughs, colds, asthma, whooping cough, and all diseases of the throat and lungs.

CAR COUPLING.—Eliza M. Hobbs, Santa Rosa. No. 267,749. Dated Nov. 21, 1882. This is a novel automatic car coupling, the invention consisting in certain details of construction difficult to clearly describe without the aid of engravings.

News in Brief.

WHOLESALE prices of coffee in New York are lower now than has been known since the panic of 1857.
